A concentration on negative duties is often associated with deontological theories (see Deontological ethics). According to such theories, morality consists largely of constraints on action, none of which we can morally violate, but which may be relevant only in a limited number of situations. Deontologists often hold that the distinction between positive and negative duties can be morally significant: the negative duties are more important or more stringent than the positive ones. Indeed, it is sometimes held that there can be a duty not to bring about something, while there is no duty to prevent it from occurring (see Double effect, principle of). For example, there might be a very stringent duty not to kill someone, while there is, at best, a much less stringent duty to save that person’s life (see Life and death).

Teleological theories, especially consequentialist ones, even if they recognize a distinction between positive and negative *actions*, generally do not consider it to underpin a difference between negative and positive *duties* that has any moral significance (see Teleological ethics; Perfectionism; Consequentialism). Such theories are concerned with the promoting of values, and it does not matter whether the values are promoted by acting or refraining from

acting. For example, if the value is respect for life, then it can be promoted equally well either by refraining from killing or by saving lives.

While it seems reasonable to think that there is some difference between positive and negative actions, that this involves a morally significant difference is much more contentious. Views about this divide roughly along the same lines as do those concerning the relative advantages of deontological and teleological theories. No doubt this will remain controversial as long as these approaches to duty compete.

An equally controversial and perhaps equally important distinction can be drawn, as it was by Ross (1930), between *prima facie* duties and 'all-in' duties (see Ross, W.D.). (*Prima facie* duties are sometimes called 'pro tanto duties' or 'duties other things being equal', while all-in duties are sometimes called 'duties proper' or 'duties all things considered'.) A *prima facie* duty is not, contrary to its literal meaning, something that merely *appears* to be a duty. Rather, to say that we have a *prima facie* duty to perform some action expresses the idea that the action involves an important moral consideration, but one that can be (morally) outweighed, or overridden, by other moral considerations. For example, assume that an agent has a choice between keeping a promise and helping someone in need, but cannot do both. Keeping the promise is a *prima facie* duty because it involves the morally important consideration of fidelity; helping the person in need is also a *prima facie* duty as it involves the morally important consideration of beneficence. The agent's all-in duty depends on the nature of all the relevant *prima facie* duties. That is, an all-in duty is what duty requires all things considered, in particular, given all *prima facie* duties.

Part of the motivation for this distinction is the idea that (all-in) duties can always be satisfied: there are never any real conflicts of duties. Using this distinction, we can attempt to explain apparent conflicts of duties in terms of conflicts of *prima facie* duties. When it seems that we have a duty to do two things, and we cannot do both, this distinction allows us to say that they are not really competing duties, but merely competing *prima facie* duties. (In some cases, of course, we would be permitted to do either, but would not have a duty to do either.) However, that all apparent conflicts of duties or moral dilemmas can be explained away in this fashion is not obvious. There seem to be situations where agents have to choose between courses of action that are so horrible that none is acceptable and the agent should feel regret no matter what is done. Whether such cases involve real conflicts of duties depends on two things. First, it depends on whether we take dilemmas to exclude there being a correct answer to the question of what duty requires. It may be that we call something a dilemma simply because the choices are so awful. Second, it depends on whether there is some inconsistency in feeling regret for doing something that was required by duty.

Regardless of the attitude that is taken to possible conflicts of duty, the notion of a *prima facie* duty faces difficulties. Foremost among these is the lack of a persuasive account of how all-in duty results from diverse *prima facie* duties. No satisfactory account has been given of the conditions under which one *prima facie* duty 'overrides' another.

The view that there is a distinction between perfect and imperfect duties is attributed to Kant (§10) (see Kantian ethics). He said that a perfect duty 'allows no exception in the interest of inclination' ([1785] 1903: 421). Although it is not clear exactly what he had in mind, one plausible view is that the distinction is between duties owed to particular individuals and duties that are not owed to anyone but which merely concern them. If we have a duty to someone, then that person has a right against us. (Kant thought that we can have duties to ourselves and may even have thought that we can have rights against ourselves.) If we have a duty that is not to anyone, then that duty does not involve a right against us. This, arguably, gives us more latitude in how to satisfy the duty. A duty not to kill is owed to each person, while a duty of charity is not owed to anyone, and can be satisfied by helping any of a number of persons. Perfect duties are usually associated with negative, stringent duties, while imperfect duties are associated with positive, less stringent duties.

Finally, if a theory allows for a difference between what a person sincerely considers to be required by duty and what is actually required by duty, then it can allow for a distinction between subjective and objective duty. Subjective duty is that which one sincerely takes to be one's duty, while objective duty is that which is actually required by duty. There are other notions closely related to subjective obligation, which are sometimes offered as accounts of subjective duty. One is the notion of that which duty probably requires; another is that which it would be most reasonable to think that duty requires. Each of the latter is distinct from subjective duty, as I have

characterized it. One may be sincere but incorrect about what duty probably requires. Also, one may have a sincere belief about what duty requires, which is not the most reasonable belief one can have.

3 The grounds of duties

Given that to have a duty is to be subject to a binding normative requirement, we might naturally wonder how it is that we could become subject to such a requirement. Who or what binds us? This, perhaps, is the most difficult and most interesting question concerning duties.

One tradition says that only God could be the source of our duties (see Religion and morality §1; Natural law). Given God's existence, it might be thought that God has authority over us and can impose duties on us. God would then have a right to our obedience. Giving us the Ten Commandments can be thought of as one way that God has imposed duties on us. If this is correct, then we have a duty to obey them. A problem with this view is that it has the implication that if God does not exist, then there are no duties. Another problem with it is that it is unclear why we are required to do as God commands. That is, it is unclear why God has authority over us. Indeed, a similar question can be asked about anyone or anything else, whether a person, institution or society, that is supposed to be able to impose duties on us. Why should we think that they have the authority to impose duties on us, or what gives them the right to tell us what to do?

Perhaps instead of having duties imposed on us by other humans, it is the structure of the universe itself that imposes the duties. On this view, duties (or moral laws) would be analogous to physical laws. Just as we are subject to physical laws, such as Newton's law of gravitation, we are subject to binding normative requirements, for example, the duty to help others who are in need. It is not that the universe has authority over us and we must obey its command, rather it is that normativity is part of the very fabric of the universe.

Various problems with this view have been raised. One is that the features of the universe that produce the duty would be very strange, unlike anything else about which we know (see Naturalism in ethics; Moral realism §6). A second is that it is difficult to see how we could learn about these duties. We do not have any perceptual experience of them, and perceptual experience is widely thought to be the way that we gain knowledge about the world (see Moral knowledge). The third objection rests on the action-guiding nature of duty. The idea is that it is a necessary feature of accepting something as being required by duty that we are to some extent motivated to do it. How is it that duties imposed on us by the structure of the world motivate us (see Moral motivation)?

If duties are not imposed by things independent of us, perhaps we impose them on ourselves. Indeed, as Kant argued, it might be that a duty can only be imposed by the person having it (see Kant, I. §9). A non-Kantian expression of a similar idea is this. Only moral agents can have moral duties. Moral agents are responsible for their actions, and being responsible for an action requires that the agent does it (see Responsibility). However, freedom is not sufficient for moral agency. For example, it seems that children are free, but not moral agents. Moral agency also requires that agents act rationally, that they act on reasons that they accept as adequate. This means an action is performed because of the nature of the action. If duties could be imposed on us by others - God, society, or the universe - then we would not be moral agents. We would not be acting on adequate reason because our reason for acting would not be the nature of the action. Instead, we would be acting because the action was imposed as a duty. It would be like obeying a command simply because it was a command and not because what was commanded was appropriate for the situation. So for something to be someone's duty, it must result from that person - only we can impose duties on ourselves. A similar point is this: moral agents have authority over themselves, but are subject to no other authority (see Autonomy, ethical).

Numerous questions can be raised about the idea that we impose duties on ourselves. Why is giving ourselves reasons for actions imposing duties on ourselves? After all, if we have authority over ourselves, can we not change our duties at will? Indeed, what is it to have authority over ourselves? A possible answer to these questions is that the second condition of moral agency, that we act rationally or act from adequate reason, provides additional normative constraints on what we can do as moral agents. In particular, this condition may require a sort of impartiality: a reason for a rational agent acting in a certain way in a particular situation must be a reason for any rational agent to act in the same way in similar situations (see Impartiality; Universalism in ethics §5).

If we were to accept that others cannot impose duties on us and we cannot impose duties on ourselves, would there be any use for the notion of duty? Is the idea of a duty, of morality itself, a fiction to be discarded? Not

necessarily. There could be other explanations of why we think that the notion of duty is relevant to our actions.

One position is that we cannot do without some notion of duty: it is a useful instrument. On such an account, the reasons for accepting a system of morality would not be moral reasons. Instead, the reasons would be ones of self-interest, or a combination of self-interest and interest in others (see Prudence §2). The idea is that people will generally be better off living in a society where there are social institutions and conventions regulating behaviour (see Contractarianism). For example, killing might be proscribed because it is to everyone's mutual advantage not to have to worry about being killed. A problem for this view is that there may be some people in a society who contribute such a small amount to the society that there is no reason to cooperate with them. Indeed, some may contribute so little that there is not even any reason to refrain from killing them.

Another approach suggests that what seem to be claims about duties, for example, that there is a duty to refrain from killing, actually are not claims at all. Since they are not claims, they cannot be true or false. They are merely expressions of attitudes. For example, if someone says, 'We have a duty to help those in need', no claim is being made; the utterance is merely the expression of a positive attitude towards helping those in need. It is as if the person said, 'Hooray for helping others' (see Emotivism). The main challenge for this view is to explain why much of moral conversation seems like reasoned argument. One strategy for dealing with this challenge is to argue that there is a logic of attitudes that mirrors the logic of claims or propositions.

In addition to the difficulties in giving an account of how we come to be subject to duties, the entire project of trying to characterize ethical concerns in terms of duties has come under criticism. One main objection is that the idea of duty is so closely connected to the idea of God as a lawmaker or imposer of duties that the concept has no place in secular philosophy (see Anscombe 1958). Another is that concentrating on duty blinds us to the rich diversity of considerations that are relevant to ethics. Instead of asking what our duties are, we should be asking how we should live (Williams 1985) (see Virtue ethics).

Duty and virtue, Indian conceptions of

*Two principal strains of ethical thought are evident in Indian religious and philosophical literature: one, central to Hinduism, emphasizes adherence to the established norms of ancient Indian culture, which are stated in the literature known as the Dharmaśāstras; another, found in texts of Buddhism, Jainism and Hinduism alike, stresses the renunciation of one's familial and social obligations for the sake of attaining enlightenment or liberation from the cycle of rebirth. The Dharmaśāstras define in elaborate detail a way of life based on a division of society into four 'orders' (*varṇas*) - priests, warriors, tradesmen and servants or labourers - and, for the three highest orders, four 'stages of life' (*āśramas*). Renunciation is valid only in the final two stages of life, after one has fulfilled one's responsibilities as a student of scripture and as a householder. The various traditions that stress liberation, on the other hand, advocate total, immediate commitment to the goal of liberation, for which the householder life presents insuperable distractions. Here, the duties of the householder are replaced by the practice of yoga and asceticism. Nevertheless, specific ethical observances are also recommended as prerequisites for the achievement of higher knowledge through yoga, in particular, nonviolence, truthfulness, not stealing, celibacy and poverty. The liberation traditions criticized the system of the Dharmaśāstras for being overly concerned with ritual and external forms of purity and condoning - indeed, prescribing - the killing of living beings in Vedic sacrifices; but it was only in the Dharmaśāstras that the notion of action solely for duty's sake was appreciated. The Hindu scripture the Bhagavad Gītā (Song of God) represents an effort to synthesize the two ideals of renunciation and the fulfilment of obligation. It teaches that one should integrate yoga and action in the world. Only when acting out of the state of inner peace and detachment that is the culmination of the practice of yoga can one execute one's duty without regard for the consequences of one's actions. On the other hand, without the cultivation of inner yoga, the external forms of renunciation - celibacy, mendicancy, asceticism - are without significance. It is inner yoga that is the essence of renunciation, yet yoga is quite compatible with carrying out one's obligations in the world.*

1 Introduction

Ethics was not a prominent topic of sectarian controversy in classical Indian philosophy. While Hindu, Buddhist and Jaina philosophers debated such things as the existence of universals, the reality of the external world and the existence of a self, they did not often argue directly about the nature of the good or right action. Each religious-philosophical tradition had its own body of sacred texts to which it appealed in defining *dharma* - that is, duty or righteousness, the way of conducting one's life so as to achieve happiness on earth and salvation after death. Given allegiance to a particular scripture, the question of how one should live was largely moot; debate centred, rather, on the epistemological question of how one can be confident that a particular scripture is authoritative. At the same time, two distinct ethical ideals are found espoused, explicitly or implicitly, throughout Indian religious and philosophical literature - the observance of duty, and renunciation. The ideal of renunciation cuts across all three major traditions. Especially in the Hindu tradition, where both ideals are represented, their conflict is an important theme and an attempt was made, in the *Bhagavad Gītā (Song of God)*, to reconcile them.

2 Duty

The emphasis on duty is represented primarily, if not exclusively, by texts of the Hindu tradition. In the *Ṛg Veda*, the oldest stratum of text (*c.*2000 BC), virtue is conformity to cosmic law (*ṛta*). That involves not only the performance of various obligatory rites on behalf of the gods, but also the observance of fidelity and rectitude in human relationships. In the Brāhmaṇas, later texts devoted to analysing and interpreting rituals, virtue is narrowly conceived as ritual excellence. The sacrifice is understood to yield its result through its own magic, by directly effecting what it symbolizes, not by honouring or ingratiating the gods to whom it is addressed. Transgression is thus merely a ritual mistake, a blunder or negligence - not an offence against a personal being to whom one owes an obligation - either in the context of the sacrifice itself or in human affairs seen as an extension thereof; and it produces a defilement, materially conceived as a taint or miasma, that can only be ritually removed. The Brāhmaṇas declare, for example, that the impurity of the most heinous deeds, even the killing of a Brahman (priest), can be wiped away by performing a horse sacrifice.

This ritualistic conception of virtue was significantly modified in the Dharmaśāstras, 'treatises on *dharma*'

(composed from about 600 BC onward), the most famous of which is the *Mānavadharmaśāstra (Laws of Manu)*. The correct performance of rituals is still important, but the highest *dharma*, according to this literature, is 'good conduct' in the broadest sense: 'Neither austerities nor [the study of] the Veda, nor [the performance of] the Agnihotra [rite], nor lavish liberality [to priests] can ever save him whose conduct is vile and who has strayed from the path [of *dharma*]' (*Vasiṣṭha dharmasūtra* 6.3). Nevertheless, *dharma* still fundamentally involves *doing* (and avoiding) certain things; it is implicitly defined as the adherence to certain norms, specifically, the norms of the ancient Indian society that referred to itself as 'the Aryas', which transmitted the Vedic literature. The Dharmaśāstras lay down the occupations of the various classes or 'orders' (*varṇas*, commonly referred to as 'castes') of Aryan society. Brahmans serve as priests and teachers; *kṣatriyas* as princes and warriors, *vaiśyas* as tradesmen and *śūdras* as labourers and servants. For the three highest, or 'twice-born', orders they prescribe four 'stages of life' (*āśramas*) - studentship, marriage, forest residence and renunciation - and specify that they are to be observed only in succession. Thus, although renunciation is part of the scheme, it is still to be undertaken only at a certain time and in a certain way, and so falls under the rubric of duty. (A well-known verse of the *Mānavadharmaśāstra* states, 'A twice-born man who seeks final liberation without having studied the Vedas, without having begotten sons, and without having offered sacrifices, sinks downwards' (6.37).) For the Brahman order in particular, the Dharmaśāstras spell out numerous restrictions intended to preserve its unique 'purity' - the avoidance of polluting agents, especially contact with people of lower orders, the avoidance of certain foods, and so forth. They also specify rules bearing on marriage and inheritance and other matters of civil law. They prescribe various sacraments to be undergone at certain junctures of life, the most important being the investiture of the sacred thread at the beginning of the period of studentship. They go into a plethora of matters of etiquette, even prescribing how to have sex and answer the calls of nature.

Western scholars have criticized the Brahmanical system of the Dharmaśāstras (so called because it was composed by Brahman literati in ancient times and describes a society in which Brahmans have ultimate authority) for considering virtue to be mere conformity to established practices without attempting to arrive at more fundamental principles by which such practices could be justified or criticized. But the Dharmaśāstras speak of, besides the *dharma* of the specific *varṇas*, 'the *dharma* common to all orders' (*sarvāśramadharma*). That includes such things as forgiveness, self-control, not stealing or lying, nonviolence, restraint of the senses, compassion, patience, freedom from anger, envy and avarice, and so on. Thus, while there is indeed a lack of reflection on the nature of virtue in general in the Dharmaśāstras, or for that matter in Indian thought as a whole, a step in that direction can be seen in the attempt to identify these more general duties - which, however, are considered to apply only to Aryas; other 'barbarian' societies are condemned simply for being non-Aryan. At the same time, the influential Mīmāṃsā school of Hindu philosophy explicitly asserted that, *dharma* being supersensible and thus unknowable by unaided reason, we can learn about it only from revelation. Moreover, one's state of mind is clearly recognized as essential to right conduct in the Dharmaśāstras; mere external conformity is not enough. The psychological sources of transgression - desire, greed, anger and delusion - are identified, and intention is said to add weight to the deed. Although mechanical expiation is still provided for - misconduct is still conceived to produce a defilement that can be washed away, and numerous purification rituals are described - remorse is also part of expiation.

The various Hindu schools of philosophy engaged in an extensive discussion of the nature of the scriptural injunction (*vidhi*) that commands one to carry out or avoid a certain act. Nyāya philosophers held that the injunction makes one aware of a means (the dharmic act) by which a certain desirable purpose can be achieved; that is, it motivates the hearer to act by implicitly appealing to the hearer's self-interest, whether it be spiritual or hedonistic. In general, a dharmic, pious life was thought to be conducive to happiness and prosperity on earth and the attainment of heaven after death; but, as we shall see, it was also considered instrumental in attaining ultimate salvation in the form of liberation from the cycle of rebirth. Bhāṭṭa Mīmāṃsā philosophers, on the other hand, believed that the *vidhi*, specifically, the ending of the optative verb of the injunctive sentence, actually *impels* the agent toward acting by virtue of its own peculiar efficacy (referred to as *śābdabhāvanā*). At the same time, an awareness of some purpose to be achieved through the act is also necessary. Prābhākara Mīmāṃsā philosophers, finally, held that a *vidhi* motivates one to act neither by *causing* one to act through the potency of its language, nor by *persuading* one to do so by suggesting the achievement of a desired end, but simply by making one aware of an obligation (*niyoga*) that one feels bound to carry out; it is followed for its own sake, without regard for the result of the act it prescribes. Understood in this way, the scriptural injunction resembles the Kantian categorical

imperative. This theory also implies that the will of the agent who carries out an injunction is free (see Mīmāṃsā).

3 Renunciation

The ideal of the renunciation (*sannyāsa*) of all familial and social obligations for the sake of enlightenment or liberation (*mokṣa*, *nirvāṇa*) from the cycle of rebirth was espoused in various classical Indian traditions and represents a rejection of the Brahmanical ideal. Already in the late Vedic texts called the Upaniṣads (800-300 BC) the sacrificial cult is called into question. Residence in heaven, to be achieved through ritual acts, is declared undesirable because it is impermanent: after the merit of one's good deeds (karma) is exhausted the soul must return to the physical world, where one again experiences suffering. The only possibility of fulfilment is to transcend embodied existence altogether; this is conceived in the Upaniṣads and the Vedānta school of philosophy, which based itself on the Upaniṣads, as a merging of the individual soul with Brahman, the ultimate reality of the universe. For the Hindu Nyāya-Vaiśeṣika school, it was the dissociation of the self from the mind and body, and hence from all conditions of consciousness. The Buddha refused to characterize *nirvāṇa* at all, suggesting that it is simply beyond human conception (see Vedānta §§1, 3; Nyāya-Vaiśeṣika §7; Nirvāṇa). Almost all liberation traditions emphasized techniques of yoga and asceticism along with renunciation - withdrawal from society and life as a celibate monk, hermit or wandering mendicant - as means of reducing the factors that determine rebirth, variously identified as ignorance, karma or desire. Even the commission of good acts was believed to bind the soul further in *saṃsāra* (the cycle of rebirth); for every action, whether bad or good, must eventually yield a retribution in the form of pleasure or pain, both of which require a body. (An exception is the case of an enlightened being, whose actions have no consequences because such a being has overcome the state of individuality.) Jainism, especially, recommended asceticism and self-mortification as means of directly reducing the load of accumulated karma (see Jaina philosophy §3).

However, the liberation traditions also acknowledged that the observance of certain moral precepts is essential for spiritual advancement. The texts of Buddhism, Jainism and Hinduistic yoga state the same pentad of commandments: nonviolence, truthfulness, not stealing, celibacy and nonpossession. It was generally believed that such observances reduce the tendencies towards passion that serve as the conditions of the fruition of karma. Overall, this list of virtues represents a critique of the ethical system of the Dharmaśāstras; it recommends universal principles over traditional, caste-specific norms and stresses intention over overt performance. (For each of the five virtues there corresponds a mental attitude to be cultivated; one should, for example, not only refrain from taking what does not belong to oneself, but also not have covetous thoughts.) Buddhist and Jaina texts in particular ridicule the *dharma* of the Brahmans because it not only reflects an obsession with external forms of purity but also actually involves injury to living beings. It is puzzling how a man could think himself good just because he bathes every time he comes into contact with a *śūdra*; it is even more incomprehensible that he could think so because he slaughters an animal in a sacrifice! One can see, however, that this critique of Brahmanical ethics is not entirely fair. Though they emphasize specific caste obligations, the Dharmaśāstras also recommend the cultivation, by all members of society, of most of the same virtues stressed in the liberation traditions (the notable exception being nonpossession, which precludes existence as a householder; celibacy in the Brahmanical scheme was reinterpreted as sexual restraint in marriage). They even advocate nonviolence, though typically they recommend it *outside* the context of the sacrifice; and it is the killing of a Brahman that is especially condemned.

It should also be kept in mind that the virtues recognized by the liberation traditions were understood chiefly as means to an end - enlightenment or liberation. It was only within the tradition of the Dharmaśāstras, specifically in the Mīmāṃsādiscussions of *vidhi* and, as we shall see, in the *Bhagavad Gītā*, that an appreciation of the ideal of action simply for duty's sake was attained. However, the emphasis Buddhism placed on nonviolence (*ahiṃsā*) and compassion (*karuṇā*) indicates that at least those virtues had more than instrumental value there. The Mahāyāna writings, in particular, stress that compassion is not to be practised out of any interest - certainly not for the sake of worldly delights, but also not even for the sake of liberation. The saints of Mahāyāna Buddhism, the Bodhisattvas, postpone disappearance into *nirvāṇa* until they have helped to enlighten all other beings: 'By his own person, like a baited hook, without partaking of any enjoyment himself, he attracts others and saves them. Thus it is said… "Charity is the enlightenment of the Bodhisattva"' (*Śikṣāsamuccaya*, BST edn, 22). The Buddhists came close to deriving nonviolence explicitly from the Golden Rule. While nonviolence is sometimes treated purely instrumentally in Indian thought - it is said in certain Jaina texts that violence must be avoided because it causes injury to *oneself*, in so far as the passions that engender it prevent the soul from attaining liberation - there is none

the less a marked tendency to view it as a duty grounded on a law of reason or insight into one's kinship with all creatures.

4 Renunciation in action

The Hindu scripture the *Bhagavad Gītā*, perhaps the single most important Indian text that relates to ethics, can be seen as an attempt to reconcile the two ideals of duty and renunciation. Contained in the epic poem the *Mahābhārata* (*c*.200 BC-AD 200, traditionally attributed to Vyāsa), the *Gītā* relates a dialogue between Kṛṣṇa (Krishna), an incarnation of the Supreme Being Viṣṇu, and the warrior Arjuna. The issue of the dialogue is whether Arjuna should participate in the great battle that is about to take place, for his own cousins lead the opposing side. Arjuna knows that his cause is just - his cousins are violent and despotic; they have deprived him and his brothers of their due portion of the kingdom - but he nevertheless feels that it would be a violation of *dharma* to be an agent of the destruction of his own friends and relatives, no matter how wrong they are. Filial duty has come into conflict with Arjuna's duty as a prince (*kṣatriya*) to preserve order in society and defend it against its enemies. In response to Arjuna's quandary, Kṛṣṇa does not enter into a discussion of the nature of virtue or universal principles of right action (as perhaps Socrates would have done) but tells Arjuna to cultivate yoga, which will enable him to rise above his situation. Yoga will provide Arjuna with clarity and equanimity, so that he is no longer confused about his duty - which Kṛṣṇa suggests is obvious, anyway: to defend society against evil - or overcome with remorse about the pain he must inflict in doing what he must do. It will bring about a state of calm and centredness from which he can carry out right action undistracted by passion; 'Yoga is skill in action', says Kṛṣṇa (2.50). Moreover, it will transform the personality, so that Arjuna will no longer act as an individual agent but yield to the forces of nature - ultimately, to God - acting through his body: 'He who thinks this self is a killer and he who thinks it is killed, both fail to understand; it does not kill, nor is it killed' (2.19). The yogin is not 'bound' by what he does; his actions do not necessitate further rebirth.

Thus the *Gītā* works out a synthesis of the ideals of duty and renunciation, proposing a new ideal of renunciation in action. Especially in the third, fourth and fifth chapters the theme of renunciation is taken up. Merely external forms of renunciation are criticized: one who physically refrains from acting but still yearns after sensual pleasures in his mind is a hypocrite (3.6). Thus, the tables are turned on the liberation traditions, which had criticized Brahmanical ethics for being formalistic. True renunciation is the state of inner yoga, a condition of complete calm, contentment and detachment. This is compatible with acting so as to carry out one's responsibilities in the world, even with observing the specific prescriptions of the Dharmaśāstras - indeed, the *Gītā* upholds the *varṇa*-*āśrama* system. In reality, all creatures are driven to act in so far as they are part of nature, which is subject to constant change - the fluctuations of 'the three *guṇas*' (basic ingredients of material nature). Kṛṣṇa, the Supreme Being, refers to his own case: 'These worlds would collapse if I did not perform action' (3.24). It is stressed, however, that action should be undertaken only for its own sake, out of a sense of duty: 'You have a right to action alone, not the fruits [of action]' (2.47). Thus, the state of yoga is essential for right action, because only in that state is one not driven by inclination. It is the detachment of yoga that makes it possible for one to act only for duty's sake. The *Gītā* also describes this state of mind in terms of considering one's actions as a sacrifice and surrendering one's actions to God.

The *Bhagavad Gītā* contains many religious teachings that do not relate directly to ethics but reflect the sectarian (Vaiṣṇava) origins of the poem. It stresses above all that Viṣṇu is the ultimate reality and that salvation can be attained only by worshipping Viṣṇu in his true form. Yet in the end, this metaphysical knowledge provides the solution to Arjuna's ethical dilemma. At a certain point Kṛṣṇa, who until then has appeared just as a fellow warrior, reveals himself to Arjuna as God. Arjuna sees the infinite within his body - innumerable gods, creatures and universes; the physical and psychological constituents of all beings; the past and the future, including even the outcome of the battle he is about to fight. Overwhelmed by Kṛṣṇa's infinite splendour, he now sees his own concerns as trivial. Realizing that his own actions are part of a vast panorama of life directed by God, he surrenders himself completely to Kṛṣṇa and prepares to fight.

Dworkin, Ronald (1931-)

Ronald Dworkin's early, highly controversial, thesis that there are right answers in hard cases in law, coupled with his attack on the idea that law is simply a system of rules, gained him a prominent and distinct place in the anti-positivist strand of legal theory. He has developed and enriched his earlier insights by tying his notion of law-as-interpretation to the ideals of community and equality. Dworkin is an influential representative of liberal thought, who combines clear and analytical thinking with political involvement expressed in decisive and timely interventions in many of the important political debates of our time.

Ronald Dworkin, born in Massachusetts, read philosophy and law at Harvard and Oxford; after a brief period in legal practice he became a professor of law at Yale in 1962. In 1969 he succeeded H.L.A. Hart as Professor of Jurisprudence at Oxford University and since 1975 has also been Professor at New York University. His ideas have been profoundly influential in developing British and US jurisprudential thought.

Since very early in his career Dworkin has queried the positivist (and particularly the Hartian) concept of law as a system of rules. Dworkin criticizes positivism for its limited and impoverishing account of law that necessarily entails judicial law-making and retrospectivity in hard cases. Dworkin argues that every judicial decision requires discretion understood as the exercise of judgment, as interpretation, and yet none requires discretion of the unrestricted type envisaged by positivists. The right legal answer cannot be 'read off' a rule but requires a justification (that subsumes the rule under it) in terms of discussing principles embodied in the law (see Legal positivism §5; Legal reasoning and interpretation §§2-4).

To his first distinction, 'rules/principles' - that underlies his attack on positivism - Dworkin adds a second, that of 'principles/policies', that underlies his attack on utilitarianism. Principles are propositions that describe rights, and to 'take rights seriously' (1978) means to always allow them to 'trump' policies. In every case a requirement of justice or fairness embodied in principle should override any competing consideration of policy associated with the pursuit of collective goals.

Both distinctions, both attacks, are present in *Law's Empire* (1986), which integrates the earlier insights in a theory of law-as-interpretation fundamentally enriched by the notion that the law is a practice and occurs in a community of interpreters. Legal interpretation requires us to appreciate that law is a practice that involves us as participants in arguing its meaning. For the interpretive attitude to take hold people must try to view the practice 'in its best light' and reconceive its requirements in the light of what would most fully realize its implied purpose. This is a requirement performed on objective ground: not by imposing upon the practice outside moral or personal purposes, but by retrieving purpose from within the practice, as it is intelligible to the people participating in the common form of life, the community.

Dworkin's theory of law-as-interpretation focuses precisely on the junction of law with the notion of community. First, as horizon and inventory, community circumscribes the ambit of possibilities of what a practice may require, locating each attempt at the best interpretation of the requirements of the practice within the context we share of its possible meanings. But debating the best among possible understandings involves the participants in an argument over the purpose or point of the practice; interpretation is always justification for Dworkin, the imputation of justificatory principle, but a principle that is already embodied in the past record of the practice, retrieved not posited. It is a kind of reflexive equilibrium between what fits the community's legal record and what morally justifies it - a balancing undertaken against the background of the whole body of the law - that yields for each case in law the right answer, which Dworkin calls 'integrity'. With neither unreflective adherence nor contempt for past legal decisions - a contempt of which Dworkin accuses his prime adversaries, the critical legal scholars - Dworkin's ideal judge secures that the community act in a consistent manner in applying its conception of justice (see Critical Legal Studies). Through the notion of integrity Dworkin can construct a concept that is true to demands of interpretation and community. Interpreting a set of social practices under the demands of integrity sustains the unity of community, elevates it from a bare to a true community and allows the fraternal attitude within to flourish.

Dworkin's work has attracted a great deal of criticism, of which we may identify four axes. The first contests his

account of interpretation. It has been argued here that Dworkin falsely assumes that interpretation ought to be a ‘best’ reconstruction when the point of interpretation is to show the practice as it actually is; that making the law more attractive than it is performs a mystifying, ideological function; and that it allows the meaning of laws to become relativized since ‘best justifications’ are - to some extent at least - subjective. The second questions the ‘dialectical’ relationship between community and the law. Why assume with Dworkin that law is constitutive of the texture of our communities, and provides the terms in which we argue our normative commitments? A third line contests the fundamental distinctions that Dworkin employs. The rules/principles distinction, it has been argued, cannot serve to refute positivism because nothing in positivism precludes principles understood in a justificatory role and as rationalizations behind rules. The privileging of principle over policy runs into the frequent difficulty of keeping the two types of political aim apart in practice. Finally it has been argued that fit cannot be meaningfully divorced from justification - a ‘fit’ is always already justified as such - and as an integral part of justification it could not at the same time constrain it. The fourth line questions Dworkin’s theory’s liberal underpinning, one that is best captured in his advocacy of law as an institution that elevates conflicts from the battleground of politics to the forum of principle (1985) in such a way that with its insistence on the maintainance of unity and of ‘fit’ within the system precludes the possibility of radical critique and change.

Dworkin’s suggestion about what it means to treat people as equals informs his intervention in the debate over reverse discrimination. His theory of distributive justice is explored in a series of articles on equality (1981a, 1981b, 1991) where he argues for equality of resources rather than equality of welfare. Dworkin is known for his interventions in many heated controversies of our time over civil disobedience, pornography, freedom of speech (1985) and abortion and euthanasia (1993). The latter is an attempt to shift the debate from the seemingly intractable disputes in the battlefield of politics towards the common ground that we share: a commitment to the sanctity of life. Thus recasting the debate unifies our political communities around a common commitment while allowing principled disagreement on the morality of abortion and euthanasia that in turn yields greater tolerance for individual choice and renews Dworkin’s image as one of the most important liberal theorists of our time.

Dynamic logics

Dynamic logics have been designed by Pratt as formal systems for reasoning about computer programs. The main ingredients discussed are programs, operations on programs, states and properties of states. In particular one can formalize that every execution of a program p *starting in state* s *terminates in a state with a given property. Thus correctness statements for programs can be dealt with. According to Segerberg (1980) programs might be viewed more generally as actions of some agent so that certain aspects of human action theory can also be formulated and studied in these systems.*

1 Motivation

In Pratt's (1976) setting the meaning of a program *p* with respect to an abstract machine $\mathcal{M}$ is taken as the transition relation $\mathcal{M}_p$ between states of $\mathcal{M}$, so that $\mathcal{M}_p$ holds for states *s* and s' (symbolized by $s\mathcal{M}_p s'$) if and only if there is a machine run according to *p* starting in state *s* and terminating in state s'. The execution of programs can be non-deterministic - another run of $\mathcal{M}$ according to *p* might well lead from the same initial state to quite a different final state. Deterministic programs are therefore special programs where the transition relation is actually a (partial) function. From already given programs one can obtain other programs by applying operations like 'first do p_1 and then p_2' (*composition*), 'do p_1 or p_2' (*nondeterministic choice*) or 'apply *p* a finite number of times' (*iteration* or *looping*). Given a certain stock of basic propositions, i.e. properties of states, one can build new propositions by taking boolean combinations of already given propositions or asking modal questions like 'does every terminating run of a program *p* starting in state *s* necessarily end in a state with property *Q*?'. Thus to every program *p* naturally corresponds a modal operator $[p]$ … to be read: 'after (each terminating execution of) *p* it is the case that … ' The proposition '*not*: $[p]$ *false*' expresses for instance at *s* that at least one run of *p* starting in *s* will terminate. Every proposition *Q* induces a test programme 'if *Q* proceed, otherwise skip' (*test*). The corresponding relation holds for *s* and s' if and only if $s = s'$ and *s* satisfies *Q*. Formalizing this situation leads immediately to propositional dynamic logic.

2 Propositional dynamic logic

The above remarks suggest the following formal language where formulas and program terms (for short: programs) are simultaneously built up from propositional and program variables with the aid of the usual propositional connectives, say $\neg$ (not) and $\rightarrow$ (implies), the *p*-necessity operator $[p]$ for programs *p*, and the program forming operations $;$ (composition), $\cup$ (choice), $*$ (iteration) and $?$ (test). The formation rules for formulas and programs are as follows:

• propositional variables are formulas and if φ and ψ are formulas and *p* is a program variable then $\neg\varphi$, $(\varphi \rightarrow \psi)$ and $[p]\varphi$ are formulas
• program variables are programs and if *p* and *q* are programs and φ is a formula then $(p;q)$, $(p \cup q)$, $p*$ and $\varphi?$ are programs.

Other propositional connectives and the *p*-possibility operator $\langle p\rangle$ are introduced by definition. For instance $\langle p\rangle$ stands for $\neg[p]\neg$. A Kripke-semantics is now easily established. A model $\mathcal{M} = (S, I)$ for this language consists of a nonempty set *S* (the set of states or 'possible worlds' of $\mathcal{M}$) and a function *I* which assigns to every propositional variable a property in *S*, i.e. a subset of *S*, and to every program variable a two-place relation in *S*, an accessibility relation. Then the truth of formulas φ in $\mathcal{M}$ at state *s* (symbolically: $\mathcal{M} \models_s \varphi$) and the interpretation of programs *p* (symbolically: $\mathcal{M}_p$) can be simultaneously defined. The interesting cases are:

- $\mathcal{M} \models_s [p]\varphi$ iff for every s', $s\mathcal{M}_p s'$ implies $\mathcal{M} \models'_s \varphi$
- $\mathcal{M}_{(p;q)} = \mathcal{M}_p \circ \mathcal{M}_q$, $\mathcal{M}_{(p\cup q)} = \mathcal{M}_p \cup \mathcal{M}_q$, $\mathcal{M}_{p*} = (\mathcal{M}_p)*$
- $\mathcal{M}_{\varphi?} = \{(s,s) \mid \mathcal{M} \models_s \varphi\}$

where $R_1 \circ R_2$ denotes the product of R_1 and R_2, i.e. $sR_1 \circ R_2 s'$ holds iff there is an s_1 such that $sR_1 s_1$ and $s_1 R_2 s'$, $R_1 \cup R_2$ denotes the set theoretical union of R_1 and R_2, and $R*$ denotes the reflexive and transitive closure of *R*, i.e. $sR * s'$ holds iff either $s = s'$ or for some natural number *n* there are $s_1, \ldots, s_n$ such that sRs_1 and $\ldots$ and $s_n Rs'$ hold. A lot of constructs known from ordinary programming languages can now be formalized,

for instance 'if φ then *p* else *q*' is $((\varphi?;p)\cup(\neg\varphi?;q))$ or 'while φ do *p*' is $((\varphi?;p)*;\neg\varphi?)$. The set of valid formulas, i.e. formulas which are true in every model at all states, can be generated (in Hilbert-style) from certain axioms by *modus ponens* and the necessititation rule. The set of all tautologies together with the formulas given by the schemas below could be chosen (after Segerberg 1980) as axioms:

- $[p](\varphi\to\psi)\to([p]\varphi\to[p]\psi)$
- $[(p;q)]\varphi\leftrightarrow[p][q]\varphi$
- $[(p\cup q)]\varphi\leftrightarrow([p]\varphi\wedge([q]\varphi)$
- $[\varphi?]\psi\leftrightarrow(\varphi\to\psi)$
- $[p*]\varphi\to(\varphi\wedge[p][p*]\varphi)$
- $[p*](\varphi\to[p]\varphi)\to(\varphi\to[p*]\varphi)$

Correctness of the system is easily verified and completeness has been proved by Gabby, Parikh and Segerberg (see Goldblatt 1987). There are also correct and complete Gentzen-type systems. The question of general validity of a formula turns out to be decidable (Fischer and Ladner 1979).

3 Dynamic predicate logic

Viewing states as the content of certain storage units $x_0,x_1,x_2,...$ they can be identified with functions assigning to each x_n its contents $s(x_n)$. Thus $s(x_n)$ denotes the object (for instance a string over an alphabet) that occupies in state *s* the *n*-th storage unit. The set of objects that are allowed to appear in some storage uni-constitutes a one- (or many-) sorted domain in which certain basic first- (or higher-) order properties and functions are fixed. Using these initial data a first- (or higher-) order possibly many-sorted modal language, known as dynamic predicate logic, can be used to describe transition phenomena initiated by programs in state sets. Simple assignments of the form $x{:=}t$ (to be read: 'set *x* equal to *t*') are often taken as the only basic programs from which all others are derived by program forming operations. A run of such a simple assignment $x{:=}t$ starting in state *s* has the effect that only the content of the storage unit *x* is 'updated' by the value of *t* and every other unit is left untouched. The resulting state s' will be denoted by $s(x/t)$. Simple assignment programs are obviously deterministic and universally terminating. Fixing a first order language with individual variables $x_0,x_1,x_2,...$ and certain relation and function symbols, a model $\mathcal{M}=(D,I)$ for such a language consists of a nonempty domain *D* and an interpretation function *I* which associates with every relation and function symbol of the language an appropriate relation or function in *D*. Every formula φ then defines a property in *S*, the set of all assignments to the variables - that is the set of all functions from $\{x_0,x_1,x_2,...\}$ to *D*. An element *s* in *S* has the φ-property iff φ is true in $\mathcal{M}$ under the assignment *s*, symbolically $\mathcal{M}\models_s\varphi$. The essential new case in defining truth is:

- $\mathcal{M}\models_s[x{:=}t]\varphi$ iff $\mathcal{M}\models_{s(x/t)}\varphi$

Therefore $[x{:=}t]\varphi$ is (under certain syntactical conditions) equivalent to $\varphi(x/t)$ which arises from φ by substituting *t* for every free occurrence of *x* in φ. Using the iteration operation it is possible to express things which in general cannot be said by any fixed number of applications of the substitution operation. For instance $[(x_1{:=}f(x_1))*]Q(x_1)$ expresses in $\mathcal{M}$ at *s* that all of

$$s(x_1),f^{\mathcal{M}}(f^M(s(x_1))),...$$

have the property corresponding to *Q* in $\mathcal{M}$. In such a language the natural numbers can now be characterized up to isomorphism by a formula. The main part of this formula says that for every *y* the program

$$(x{:=}0;\ \text{while } x\neq y \text{ do } x{:=}x+1)$$

terminates (at least once). This means that every element can be reached in finitely many steps from 0 by adding 1 each time. Here iteration is used essentially. From the characterizability of the natural numbers it follows in particular that the set of valid formulas is not recursively enumerable so that no usual proof system can be correct and complete. However, by adding an infinitary rule (a sort of ω-rule) correctness and completeness can be re-established.

Dynamic predicate logic can be viewed as a sublogic of an extended predicate logic in which countable

conjunctions and disjunctions are allowed. That is because a formula $[p*]\varphi$ is obviously equivalent of the disjunction over the set of formulas.

$\varphi, [p]\varphi, [(p;p)]\varphi, [((p;p);p)]\varphi, [(((p;p);p);p)]\varphi, \ldots$

Many variations of the core formalism are possible; for instance tests are often restricted to Boolean combinations of atomic formulas. This seems to be more realistic since tests of the form $(\forall x\varphi)?$ might involve a search through an infinite domain. Also, random assignments (written as $x:=?$) are sometimes introduced. In a model $\mathcal{M} = (D, I)$ such a basic random assignment denotes the relation which holds between two assignments *s* and s' if and only if $s' = s(x/d)$ for some $d \in D$. The formula $\forall x\varphi$ can then be expressed by $[x:=?]\varphi$.

East Asian philosophy

Sinitic civilization, which includes the Chinese-influenced cultures of Japan and Korea, established an early lead over the rest of the world in the development of its material culture - textiles, iron casting, paper, maritime arts, pottery, soil sciences, agricultural and water technologies, and so on. For centuries after the first sustained incursions of Europe into East Asia, there were more books printed in the classical Chinese language - the 'Latin' of East Asia - than in all of the rest of the world's languages combined. As recently as the beginning of the industrial revolution in the eighteenth century, it was China rather than Europe which, by most standards, was the arbiter of science and civilization on this planet.

If 'philosophy'- the pursuit of wisdom - is an aspiration of high cultures generally, why then was it not until the late nineteenth century, in response to a growing relationship with Western learning, that an East Asian term for 'philosophy' was coined, first by the Japanese (*tetsugaku*), and then introduced into Chinese (*zhexue*) and Korean (*ch'ôlhak*)? If it would be absurd to suggest that East Asian cultures have no history, no sociology, no economics, then how do we explain the fact that Asian philosophy is a subject neither researched nor taught in most Anglo-European seats of higher learning?

1 Uncommon assumptions, common misconceptions

The prominent French sinologist Jacques Gernet (1985) argues that when the two civilizations of China and Europe, having developed almost entirely independently of each other, first made contact in about 1600, the seeming resistance of the Chinese to embracing Christianity and, more importantly, the philosophic edifice that undergirded it was not simply an uneasy difference in the encounter between disparate intellectual traditions. It was a far more profound difference in mental categories and modes of thought, and particularly, a fundamental difference in the conception of human agency. Much of what Christianity and Western philosophy had to say to the East Asians was, quite literally, nonsense - given their own philosophic commitments, they could not think it. In turn, the Jesuits interpreted this difference in ways of thinking quite specifically as ineptness in reasoning, logic and dialectic.

The West has fared little better in its opportunity to appreciate and to appropriate Sinitic culture. In fact, it has fared so badly that the very word 'Chinese' in the English language, found in illustrative expressions from 'Chinese revenge' and 'Chinese puzzle' to 'Chinese firedrill', came to denote 'confusion', 'incomprehensibility' or 'impenetrability', a sense of order inaccessible to the Western mind. The degree of difference between a dominant Western metaphysical sense of order and the historicist 'aesthetic' order prevalent in the radial Sinitic world view has plagued the encounter between these antique cultures from the start. When seventeenth-century European savants such as Leibniz and Wolff were looking to corroborate their universal indices in other high cultures - the one true God, impersonal rationality, a universal language - China was idealized as a remarkable and 'curious land' requiring the utmost scrutiny. In the course of time, however, reported on by philosophers such as Kant, Hegel, Mill and Emerson, Western esteem for this 'curious land' plummeted from such 'Cathay' idealizations to the depths of disaffection for the inertia of what, in the context of the Europe-driven industrial revolution, was recast as a moribund, backward-looking and fundamentally stagnant culture.

In classical Chinese there is an expression: 'We cannot see the true face of Mount Lu because we are standing on top of it.' Although virtually all cultural traditions and historical epochs are complex and diverse, there are certain fundamental and often unannounced assumptions on which they stand that give them their specific genetic identity and continuities. These assumptions, extraordinarily important as they are for understanding the cultural narrative, are often concealed from the consciousness of the participants in the culture who are inscribed by them, and become obvious only from a perspective external to the particular tradition or epoch. Often a tradition suspends within itself competing and even conflicting elements which, although at odds with one another, still reflect a pattern of importances integral to and constitutive of its cultural identity. These underlying strands are not necessarily or even typically logically coherent or systematic, yet they do have a coherence as the defining fabric of a specific and unique culture.

Looking at and trying to understand elements of the East Asian cultural narrative from the distance of Western traditions, then, embedded as we are within our own pattern of cultural assumptions, has both advantages and

disadvantages. One disadvantage is obvious and inescapable. To the extent that we are unconscious of the difference between our own fundamental assumptions and those that have shaped the emergence of East Asian philosophies, we are sure to impose upon this geographical area our own presuppositions about the nature of the world, making what is exotic familiar and what is distant near. On the other hand, a clear advantage of an external perspective is that we are able to see with greater clarity at least some aspects of 'the true face of Mount Lu': we are able to discern, however imperfectly, the common ground on which the Confucian and the Buddhist stand in debating their differences, ground which is in important measure concealed from they themselves by their unconscious assumptions.

2 One-world natural cosmology

In the dominant world view of classical East Asia, we do not begin from the dualistic 'two-world' reality/appearance distinction familiar in classical Greek metaphysics, giving rise as it does to ontological questions such as: 'What is the Being behind the beings?' Rather, we begin from the assumption that there is only the one continuous concrete world that is the source and locus of all of our experience, giving rise to cosmological and ultimately ethical questions such as: 'How do these myriad beings best hang together?' Order within the classical East Asian world view is 'immanental' and 'emergent', an indwelling regularity in things themselves. It is the always unique yet continuous graining in wood, the distinctive striations in a piece of jade, the regular cadence of the surf, the peculiar veining in each and every leaf. The power of creativity resides in the world itself. The order and regularity this world evidences is neither derived from nor imposed upon it by some independent, activating power, but inheres in the world itself. Change and continuity are equally 'real'; time itself is the persistence of this self-transformation.

The 'one' world, then, is the efficient cause of itself. Situation takes priority over agency; process and change take priority over form and stasis. The context itself is resolutely dynamic, autogenerative, self-organizing and, in a real sense, alive. This one world is constituted as a sea of *qi*, psychophysical energy that disposes itself in various concentrations, configurations and perturbations (see Qi). There is an intelligible pattern (see Li) that can be discerned and mapped from each different perspective within the world (see De) that is its *dao*, a 'pathway' which can, in varying degrees, be traced out to make one's place and one's context coherent (see Dao). *Dao* is, at any given time, both *what* the world is and *how* it is, always as entertained from some particular perspective or another. In this tradition, there is no final distinction between some independent source of order, and what it orders. There is no determinative beginning or presumptive teleological end. The world and its order at any particular time is self-causing, 'so-of-itself' (*ziran*) (see Chinese philosophy; Daoist philosophy; Daodejing; Zhuangzi). Truth, beauty and goodness as standards of order are not 'givens': they are historically emergent, something done, a cultural product. Given the priority of situation over agency, there is a continuity between nature and nurture, a mutuality between context and the human being. In such a world, it is not unexpected that the *Yijing (Book of Changes)* is the first among the ancient classics (see Yijing).

3 *Ars contextualis*: the art of contextualizing

The 'two-world' metaphysical order inherited out of classical Greece has given the Western tradition a theoretical basis for *objectivity* - the possibility of standing outside and taking a wholly external view of things - a 'view from nowhere'. Objectivity is not only the basis for such universalistic claims as objective truth, impersonal reason and necessity, but further permits the decontextualization of things as 'objects' in our world. It is the basis on which we can separate objective description from subjective prescription.

By contrast, in the 'one world' of classical East Asia, instead of starting abstractly from some underlying, unifying and originating principle, one begins from one's own specific place within the world. Without objectivity, 'objects' dissolve into the flux and flow, and existence becomes a continuous, uninterrupted process. Each person is invariably experiencing the world as one perspective within the context of many. Since there is only the one world, we cannot get outside of it. From the always unique place one occupies within the cosmos of classical East Asia, one construes and interprets the order of the world around one as contrasting 'thises' and 'thats'- 'this person' and 'that person' - more or less proximate to oneself. Since each and every person or thing or event is perceived from some position or other, and hence is continuous with the position that entertains it, each thing is related to and a condition of every other.

In the human world, all relationships are continuous from ruler and subject to friend and friend, relating everyone as an extended ‘family’. Similarly, all ‘things’, like all members of a family, are correlated and thus interdependent. Every thing is holographic in entailing all other things as conditions for its continued existence, and is what it is at the pleasure of everything else. Whatever can be predicated of one thing or one person is a function of a network of relationships, all of which combine to give it its role and to constitute its place and its definition.

There is no strict notion of identity that issues forth as some essential defining feature - a divinely endowed soul, rational capacity or natural locus of rights - that makes all human beings equal. In the absence of such equality, the various relationships which define one thing in relation to another are qualitatively hierarchical and contrastive: bigger or smaller, more noble or more base, harder or softer, stronger or weaker, more senior or more junior. Change in the quality of relationships between things always occurs on a continuum as movement between such polar oppositions.

The general and most basic language for articulating such correlations among things is metaphorical: in some particular aspect at some specific point in time, one person or thing is ‘overshadowed’ by another; that is, made *yin* to another’s *yang*. Literally, *yin* means ‘shady’ and *yang* means ‘sunny’, defining in the most general terms those contrasting and hierarchical relationships which constitute indwelling order and regularity (see Yin-yang).

It is important to recognize the *interdependence* and correlative character of the *yin-yang* kind of polar opposites, and to distinguish this contrastive tension from the dualistic opposition implicit in the vocabulary of the classical Greek world, where one primary member of a set such as Being transcends and stands *independent* of, and thus is more ‘real’ than the world of Becoming. The implications of this difference between dualism and correlativity contrast are fundamental and pervasive.

To continue the ‘person’ example, generally in East Asian philosophy, a particular person is not a discrete individual defined in terms of some inherent nature, but is a centre of constitutive roles and relationships. These roles and relationships are dynamic, constantly being enacted, reinforced and ideally deepened through the multiple levels of natural, cultural and social discourse. By virtue of these specific roles and relationships, a person comes to occupy a place and posture in the context of family, community and world. The human being is not shaped by some given design which underlies natural and moral order in the cosmos, and which stands as the ultimate objective of human growth and experience. Rather, the ‘purpose’ of the human experience, if it can be so described, is more immediate; it is to coordinate the various ingredients which constitute one’s particular world here and now, and to negotiate the most productive harmony out of them. Simply put, it is to get the most out of what you have here and now.

4 Radial harmony

A major theme in Confucianism, foundational throughout East Asia, is captured in the phrase from *Analects* 13.23, ‘the exemplary person pursues harmony (*ho*), not sameness’ (see Confucian philosophy, Chinese; Confucian philosophy, Japanese; Confucian philosophy, Korean; Neo-Confucian philosophy). This conception of ‘harmony’ is explained in the classical commentaries by appeal to the culinary arts. In the classical period, a common food staple throughout northern Asia was *keng*, a kind of a millet gruel in which various locally available and seasonal ingredients were brought into relationship with one another. The goal was for each ingredient - the cabbage, the radish, the bit of pork - to retain its own colour, texture and flavor, but at the same time to be enhanced by its relationship with the other ingredients. The key to this sense of harmony is that it begins from the unique conditions of a specific geographical location and the full contribution of those particular ingredients readily at hand - *this* piece of cabbage, *this* fresh, young radish, *this* tender bit of pork and so on - and relies upon artistry rather than recipe for its success.

The Confucian distinction between an inclusive harmony and an exclusive sameness has an obvious social and political application, underscoring the fertility of the kind of harmony that maximizes difference. This ‘harmony’ is not a given in some preassigned cosmic design, but is the quality of the combination at any one moment created by effectively correlating and contextualizing the available ingredients, whether they be foodstuffs, farmers or infantry. It is not a quest of discovery, grasping an unchanging reality behind the shadows of appearance, but a profoundly creative journey where the quality of the journey is itself the end. It is the attempt to make the most of

any situation.

In summary, at the core of the classical East Asian world view is the cultivation of radial harmony, a specifically ‘centre-seeking’ or ‘centripetal’ harmony which is productive of consensus and orthodoxy. This harmony begins from what is most concrete and immediate - that is, from the perspective of any particular human being - and draws through patterns of deference from the outside in toward its centre. Hence there is the almost pervasive emphasis on personal cultivation and refinement as the starting point for familial, social, political and cosmic order (see Self-cultivation in Chinese philosophy). A preoccupation in classical East Asian philosophy, then, is the cultivation of this centripetal harmony as it begins with oneself, and radiates outward.

The East Asian world view is thus dominated by this ‘bottom-up’ and emergent sense of order which begins from the coordination of concrete detail. It can be described fairly as an ‘aestheticism’, exhibiting concern for the artful way in which particular things can be correlated efficaciously to thereby constitute the *ethos* or character of concrete historical events and cultural achievements. Order, like a work of art, begins with always unique details, from ‘this bit’ and ‘that’, and emerges out of the way in which these details are juxtaposed and harmonized. As such, the order is embedded and concrete - the colouration that differentiates the various layers of earth, the symphony of the morning garden, the wind piping through the orifices of the earth, the rituals and roles that constitute a communal grammar to give community meaning. Such an achieved harmony is always particular and specific, and is resistant to notions of formula and replication.

5 Philosophical syncreticism

As one might expect in a cultural narrative which privileges interdependence and the pursuit of radial harmony, orthodoxy is neither exclusive nor systematic. Rather, traditions are porous and syncretic. In the Han dynasty, for example, Confucianism is first fortified by elements appropriated from the competing schools of pre-Qin China such as Daoism and Legalism (see Legalist philosophy, Chinese). Later it absorbs into itself an increasingly Sinicized Buddhist tradition, evolving over time into a neo-Confucianism (see Neo-Confucian philosophy). At the same time, the *shuyuan* acadamies established by the great neo-Confucian syncretist Zhu Xi are modelled on Buddhist monastic schools. In more recent years the Western heresy, Marxism, and other elements of Western learning such as the philosophy of Kant and Hegel, are being appropriated by China and digested to produce what today is being called the ‘New Confucianism’ (see Marxism, Western; Marxism, Chinese).

The indigenous shamanistic tradition of Korean popular religion absorbed first Buddhism and then Confucianism from China, reshaping these traditions fundamentally to suit the uniqueness of the Korean social and political conditions (see Buddhist philosophy, Korean; Confucian philosophy, Korean). Native Japanese Shintoism emerges as a distinction made necessary by the introduction of first Buddhism and then Confucianism, where each tradition assumes a complementary function within the culture (see Shintō; Confucian philosophy, Japanese; Buddhist philosophy, Japanese). More recently, in the work of Kyoto School thinkers such as Nishida, Tanabe and Nishitani, German idealism is mined and alloyed with the Japanese Buddhist tradition to produce new directions.

Although Confucianism, Buddhism and Daoism - the dominant traditions of East Asia - have certainly been rivals at one level, it has been characteristic of the living philosophical traditions defining of East Asian culture to pursue mutual accommodation through an ongoing process of encounter and appropriation; hence the familiar expression *sanjiao weiyi*, ‘the three teachings (Confucianism, Buddhism and Daoism) are as one’. A continuation of this process is presently underway with the ongoing East Asian appropriation of Western philosophy.

Eberhard, Johann August (1739-1809)

A German philosopher and theologian, Eberhard was trained in the rationalist tradition of Christian Wolff, but was also influenced by the more empirical 'popular philosophy' of the Enlightenment. Although a prolific author, who wrote on virtually every area of philosophy, he is best known today for his controversies with the two foremost German thinkers of his time, Gotthold Ephraim Lessing and Immanuel Kant.

Born in Halberstadt, Eberhard studied theology at Halle and entered the ministry in 1763. In 1778 he was appointed professor of philosophy at Halle and in 1786 he became a member of the Berlin Academy.

The controversy with LESSING was initiated by the publication of his first work, *Neue Apologie des Socrates (New Apology of Socrates)* (1772-8). Here Eberhard defended the heretical doctrine of the salvation of virtuous pagans (such as Socrates) and attacked the orthodox doctrines of original sin and eternal punishment. He also accused Leibniz of insincerity for his defence of the latter doctrine in his *Theodicy*. The attack on Leibniz occasioned Lessing's reply, which consists of an ironical defence of both Leibniz and the doctrine of eternal punishment, as well as a critique of what he took to be Eberhard's superficial rationalism. Eberhard responded to Lessing in the second volume of the *Neue Apologie*.

After this, Eberhard turned his interest to philosophy and published his *Allgemeine Theorie des Denkens und Empfindens (General Theory of Thinking and Sensing)* (1776). Although deeply influenced by Leibniz's *Nouveaux essais (New Essays)* (1704), he criticized Leibniz's account of innate ideas and defended Locke's view that all ideas derive from experience (see LOCKE, J.). The work was immediately successful, resulting in a prize from the Berlin Academy and the appointment at Halle. He was also quite successful as a teacher and exerted considerable influence on the young Friedrich Schleiermacher. He also published several handbooks on various aspects of philosophy, based largely on his lectures.

Eberhard initiated the controversy with Kant through his editorship of the *Philosophisches Magazin* (1789-91) and the *Philosophische Archiv* (1792-5). In these journals, which were created expressly to attack the Kantian philosophy, he published numerous articles, mostly written by himself and his colleague, J.G. Maass, criticizing major tenets of the *Critique of Pure Reason* (1781/1787) from a Leibnizian standpoint. The central theme of these articles is the superiority of the Leibnizian to the Kantian philosophy. It is claimed that whatever is true in Kant is already to be found in Leibniz and that wherever Kant departs from Leibniz he is wrong. In the course of arguing for this, however, Eberhard and Maass also raise important objections to Kant's distinction between analytic and synthetic judgments, the doctrine of the ideality of space and time, and the concept of an unknowable thing in itself. Kant, who usually refrained from engaging in direct polemics, made an exception in this case and responded in his *On a Discovery According to which Any New Critique of Pure Reason is Rendered Dispensable by an Older One* (1790). Eberhard is thus to be credited with occasioning this very significant clarification of Kant's views.

Ecological philosophy

In the early 1970s a small number of academic philosophers in the English-speaking world began to turn their attention to questions concerning the natural environment. Environmental philosophy initially encompassed various types of inquiry, including applied ethics oriented to issues such as nuclear power and the deployment of toxic chemicals; more abstract extrapolations of traditional ethical theories, such as Kantianism and utilitarianism, into environmental contexts; and, also, a far more radical project involving the reappraisal of basic presuppositions of Western thought in the light of their implications for our relation to the natural world. The first two were basically extensions of existing areas of philosophy, and it is arguably the third project - often described as 'ecological philosophy' or 'ecophilosophy' - which constitutes a distinctively new branch of philosophy. It is to environmental philosophy in this third sense that the present entry is devoted.

Although the ecophilosophical project was explicitly normative in intent, it was quickly found to entail far-reaching investigations into the fundamental nature of the world. Indeed it was seen by many as entailing a search for an entirely new ecological paradigm - a worldview organized around a principle of interconnectedness, with transformative implications for metaphysics, epistemology, spirituality and politics, as well as ethics. Moreover, the process of elaborating a new ecological view of the world was found to uncover the contours of an already deeply embedded worldview, organized around a principle of separation or division, underlying and shaping the traditional streams of modern Western thought.

1 Origins of ecophilosophy

In its earlier phases ecophilosophy was primarily (though not exclusively) associated with a movement known as 'deep ecology', a term coined in 1973 by the Norwegian philosopher Arne Naess. Naess contrasted 'shallow environmentalism', which sought environmental reform within existing philosophical and ideological parameters, with the 'deep, long-range ecology movement', which involved challenging prevailing philosophical and ideological assumptions about our relation to the natural world. Naess provided his own versions of these challenges and gave his own responses to them, but arguably his most important contribution to environmental philosophy has been to open up this new horizon and to reveal the radical potential of the ecological approach.

Ecophilosophy can no longer be encompassed within the various 'platforms' of deep ecology initially enunciated by Naess and his followers. However, although the 'deeper' questions that ecology poses are now being explored in a variety of ways, many ecophilosophers agree on the broad outlines of the hitherto dominant worldview and its emerging ecological alternatives.

2 The classical scientific worldview

The dominant worldview is sometimes called Newtonian, sometimes Cartesian. It was forged during the scientific revolution of the seventeenth and eighteenth centuries, though it is often seen as having antecedents in both classical Greek thought and Christianity. It is Newtonian insofar as it is atomistic and mechanistic, and Cartesian insofar as it is dualistic. From a Newtonian point of view, the natural world is made up of *atoms* - discrete particles, units that exist independently of one another. It is built like a machine out of aggregates held together not by any mutual affinity or intrinsic dynamism but purely *mechanically*, by blind, external laws of motion. (Gravitation was an anomaly for Newton' an 'occult' force which vitiated the simplicity of the mechanistic picture.) Such an atomistic world is fully quantifiable and hence describable in mathematical terms, since it can be reduced to nothing but countable units in measurable spatial relations. It is nothing but the mechanical sum of its inert parts.

To characterize the natural world in this way drained it of all of the attributes associated with mind - attributes such as agency, the power of self-mobilization, subjectivity, soul, meaning and purpose. It followed either that mind was illusory, a phenomenon which, as Hobbes argued, could be reduced to mechanism, or that mind was no part of the natural system, but, as Descartes claimed, a distinct category of substance, ontologically independent of matter (see Substance §2).

It was the Cartesian *dualism*, rather than the Hobbesian reduction, which came to inform the worldview that emerged from classical science. Mind, banished from matter' took up its dwelling place in us. Because the world

in which we exist was considered to be made up of discrete parts, none of which was intrinsically connected with any other, mind could indeed be sealed away in human brains in this way, and, so to speak, not leak out into the surrounding world. This cultural preference for the Cartesian over the Hobbesian view might perhaps be attributed to the fact that the nihilism implicit in Hobbes was relatively unlivable, whereas the Cartesian approach was ideologically appealing.

For if humanity was the repository of all meaning and purpose, then it was also the exclusive locus of value; matter as the inert and dead, the purposeless and blind, possessed only the meaning and hence value that we projected onto it This flattering image of humanity as categorically elevated above the rest of nature had an obvious appeal in an expansive and ambitious age. Moreover, the natural world, divested of intrinsic value, was rendered a fit object for human use, significant only as a reservoir of resources for humankind. This dissolution of traditional constraints on the exploitation of the natural environment obviously suited the mercantile ends of the early modern era.

In reinforcing the assumption that humanity is the only proper object of moral concern and the only yardstick of meaning and value in life, the scientific worldview is seen by ecophilosophers as entrenching the human centredness or *anthropocentrism* that was to a certain extent already, in the pre-modern period, characteristic of Western thought, with its Judaeo-Christian and classical Greek and Roman origins.

Ultimately, the classical scientific worldview and the anthropocentrism which accompanies it may be seen to rest on a fundamental principle of division or separation: reality at every level, indeed thought itself, is separated out into units, or divided into opposing categories. Not only is the natural world divided into atoms, and mind divorced from body, but God, as spirit, stands apart from and above the realm of matter; the epistemic subject is constituted by its separation and strict 'detachment' from the object; society is seen as the sum of the discrete and autonomous individuals which are its units; thought proceeds by analysis, by the consideration of parts.

3 Ecological worldviews

If the 'dominant worldview' emphasizes separation, alternative, ecological worldviews rest on a principle of interconnectedness. 'Ecology' is not intended here in its literal sense, as denoting merely a branch of biological science. The science of ecology, with its representation of the living world as a system of relationships, is in itself neutral with respect to its deeper metaphysical implications. In ecophilosophy, however, this science serves as a *model* - an appropriate theoretical image for a set of irreducible ontological interdependencies.

From this ecological perspective, the world is not seen as divided into mutually independent parts and mutually exclusive attributes: everything is seen as implicating, and being implicated in, the identities of other things, reality being a relational system of shared, interpenetrating essences. Since the properties of a given individual are a function of its relations with individuals of countless other kinds, these properties do not belong exclusively to it: each individual owes its nature to others in the network. It follows that meaning-giving and value-endowing qualities such as mind or subjectivity or soul, and the value that accompanies them, cannot be monopolized by human beings, but must be diffused throughout the systems of the natural world.

In restoring to reality its intrinsic interconnectedness, the ecological perspective implies that since non-human others are implicated in our identity, they are also implicated in our ends and interests, and hence in our conception of the good. In reanimating the world with a quality analogous to mind, this perspective furthermore implies that nature is morally significant in its own right, and is not merely a stockpile of resources for humankind. Such an *ecocentric* perspective situates humanity *in* nature rather than apart from and above it, and thereby removes the traditional justification for anthropocentric attitudes. The idea of interconnectedness can function as an organizing principle not only within metaphysics and ethics, but in many different theoretical and practical contexts. For example, from the interconnected perspective, the epistemic subject is not constituted by way of separation or detachment from its object. Rather, the subject seeks understanding of 'the other' through empathy, affinity, a sense of kinship - through dialogue rather than the objectifying gaze of traditional science. In the theological context, spirit is seen as immanent in matter, body, Nature. Spirituality thus involves celebration of and reverence for our corporeal existence, and affirmation of the natural world and our enmeshment in it. In the sociopolitical context, society is seen not as an aggregate of social atoms - essentially mutually independent individuals - but as a collective, in which individuals are constituted through their relations with one another.

The idea of interconnectedness, however, has been interpreted in different ways by different authors. Perhaps the most important divergence is that between broadly holistic and relational interpretations. According to the more holistic interpretations, interconnectedness implies that individuals exist or are significant only at the level of appearance: individuality lacks ultimate ontological significance. In this case, the individual may be seen as ’one with’ the greater whole.

The holistic interpretation can itself be read in two ways. Either I see nature as an extension of myself, so that its interests become indistinguishable from my interests, and ’eco-defence’ becomes a matter of self-defence. Or I see myself as an outgrowth or expression of nature, a purely natural phenomenon, so to speak, without independent identity or interests In this case I substitute nature’s interests for my own. From this holistic point of view then, I either absorb nature conceptually into myself, or lose myself in nature. Holistically oriented ecophilosophers have tended to opt for the former reading.

According to the more relational interpretations of interconnectedness, individuals are real, but their reality is a function of their relationships: it is through their interactions that they maintain themselves and define their boundaries. The natural world thus appears not as a field or continuum, but as a community, in which individuals are internally related, in the manner of a family, but are nevertheless distinct. It is incumbent on us, from this point of view, to recognize our kinship with other individuals, but also to respect their otherness. Empathy is required, but not outright identification.

The holistic interpretation of interconnectedness has been identified, by certain critics, with deep ecologists. Some feminists have argued that metaphysics recapitulates psychology, in the sense that different views of the structure of the world emanate from different ego psychologies. In particular, the atomistic outlook is taken to reflect a psychology of separateness associated, in certain (‘object relations’) branches of feminist psychoanalytic theory, with the masculine self, while a relational outlook is taken to reflect a relational psychology associated with the feminine self. Some feminists argue that when ecophilosophers postulate an holistic metaphysic, in an attempt to escape the alienation of the atomistic self, they inadvertently perpetuate this alienation, by replacing the isolated local self with an inflated but still isolated global self. From this point of view, then, true interconnectedness calls for relationality rather than holism, for self-in-relation rather than the expansion of self into a greater unity.

Alhough there is much ongoing ambivalence among ecophilosophers as to the exact nature of ecological interconnectedness, the holistic and relational interpretations (and the relational form of individualism that the latter interpretation implies) may be construed as complementary: interconnectedness may be seen as entailing the identities of both wholes and (relational) individuals. Individuals may be seen as energy configurations or sub-systems which maintain their integrity by continuous give and take with the wider system within which they are nested. Their relationality thus entails their individuality, but the relational constitution of the wider system ensures that that system, too, possesses an inherent unity and integrity which makes it an indivisible whole.

4 Three streams of ecophilosophy

Three broad streams of ecophilosophy have emerged to date, though a number of individual ecophilosophers remain unaffiliated with any of them. These streams are deep ecology, ecofeminism and social ecology, and though all are broadly ecocentric in their outlook, their critiques of the dominant worldview and their elaborations of the idea of ecological interconnectedness differ to a certain extent. They each impute the contemporary environmental crisis to the anthropocentric underpinnings of Western thought; but they offer somewhat competing analyses of this anthropocentric premise and differently nuanced remedies for it.

While deep ecologists have been most effective in bringing the problem of anthropocentrism to light, they have generally been less concerned than either ecofeminists or social ecologists with analysing its origins in the Western tradition. This relative lack of concern reflects a shying away, in deep ecology, from systematic approaches generally. Early in the development of deep ecology, Naess drew a distinction between deep ecology as a ’platform’, on the one hand, and deep ecology as a collection of ’ecosophies’, on the other. The deep ecology platform, which served as the manifesto for deep ecology as a radical political movement, consisted of an (evolving) set of principles on which all who counted themselves deep ecologists could agree. These principles have in the past included such propositions as that all beings have an equal right to live and blossom (’biocentric egalitarianism’), and that the wellbeing and flourishing of non human life on earth has intrinsic value.

’Intrinsic value’ is here understood as value which is independent of the usefulness of non human life for narrow human purposes (see Values). An ecosophy is any philosophical theory or tradition which can ground this set of principles (see Drengson and Inoue 1995).

Naess’ own ecosophy is an amalgam of various influences, including Spinoza, Gandhi, logical positivism and the nature-centredness of the Norwegian folk tradition. It is articulated by Naess as a philosophy of ‘self-realization’, according to which individuals can overcome their culturally acquired alienation from the natural world by recognizing the ultimate ontological seamlessness of reality, and gradually identifying themselves with wider and wider circles of being, until their sense of self encompasses not only the personal ego, but family, community, bio-region, land, society at large and eventually the planet as a whole. As they realize this larger Self, individuals will perceive their own interests as converging with those of the rest of life.

Ecofeminists tend to trace the human/nature split that defines anthropocentrism to a mind/body dualism which has its earliest origins in antiquity. Like ecophilosophers generally, they recognize the importance of resolving this schism, of making the partitioned world whole again, and of re-animating a ‘dead’ nature. However, ecofeminists identify the mind/body divide as part of a wider, indeed comprehensive system of dualistic thought, the purpose of which is to divide the world conceptually into mutually opposing and hierarchically ranked categories. This system revolves around certain core dichotomies, which, in addition to mind/body, include spirit/matter, subject/object, culture/Nature, reason/emotion and reason/instinct. Under the influence of these dualistic categories, Western culture has, over approximately the last 2000 years, developed a view of the world as divided into things which possess mind or reason and things which lack it, where the former are set above the latter, and the moral significance of the latter is discounted. Reason is paradigmatically aligned with humankind, and unreason with a mechanical nature, which can accordingly then be subjected to the kinds of instrumental and exploitative attitudes that have led to the current environmental crisis.

Ecofeminists, unlike deep ecologists, offer a political analysis of the dualistic system of thought: this system serves as the naturalizing and legitimating framework for hierarchical political regimes. Theorists such as Val Plumwood (1993) show that the reason/nature dichotomy is used not only to elevate humanity above nature, but to rank one group above another within society: different social groups are assessed according to their perceived relative identifiability, or otherwise, with reason or mind. Thus, in Western cultures, men have traditionally appropriated reason (and hence mind, spirit, intellect and the subject position), while women have been consigned to nature (and hence to the body, matter, emotion, instinct and the object position). White colonizers have identified themselves with reason (civilization, science, enlightenment) and adopted the masculine subject position, while identifying the colonized with nature (primitivism, superstition, barbarism), thereby relegating them to the object position. So, too, with the ruling classes in capitalist societies; they have defined themselves in terms of reason (mental work), while defining workers in terms of the body or nature (manual work). Other groups of oppressors characterize themselves, and those they oppress, according to the same self-serving dualistic logic.

The dualistic construction of nature, with its disastrous consequences for the environment, can thus be seen as an ideological instrument of political oppression. From this point of view nature cannot be ideologically rehabilitated until the political agenda that is served by its being rendered inferior is exposed and addressed. At the same time, however, political oppression cannot be eliminated until the assumption that there exists anything corresponding to the idea of a pure object, to which subordinated groups can be conceptually assimilated, is rejected. In other words, we must respect and engage with nature as a subject in its own right, before we can respect and engage with the social ’other’ whose subjectivity has also been denied.

From this kind of ecofeminist perspective, environmentalism is inextricably linked with other social movements, such as those against sexism, racism and class oppression: ideologies of gender and race and class cannot be recast without an overhaul of our understanding of nature, and the ideological rehabilitation of nature cannot be achieved without the concurrent rehabilitation of women, colonized races, and other oppressed groups.

The approach of social ecology to the problem of anthropocentrism closely parallels that of the kind of ecofeminism just outlined. Murray Bookchin, the main architect of social ecology, argues (1982) that the human impulse to dominate Nature is formed in hierarchical societies, and will not be overcome until the social conditions which generate ’epistemologies of rule’ or psychologies of domination are corrected. This will not occur, according to Bookchin, until hierarchy in all its forms - familial, gerontological, institutional as well as political -

is eradicated from society.

Like ecofeminists and deep ecologists, Bookchin regards nature as a field of relations holistically imbued with an active attribute which confers upon it meaning and moral significance. He describes this attribute as ’subjectivity’. However, unlike ecofeminists and deep ecologists, Bookchin emphasizes the evolutionary aspect of ecology: Nature is not just an assemblage of interrelated parts but a process whereby new and more complex unities are continually being generated through increased differentiation of their elements. In other words, an ecosystem is constituted not only through its internal relations, but also through its history and its telos. In light of this recognition of the evolutionary drive towards ever greater complexity, Bookchin draws a qualitative line between humankind and nature. While human subjectivity (’second nature’) is ontologically continuous with the subjectivity of the non human realm (’first nature’), inasmuch as it derives from and recapitulates the latter, it nevertheless transcends it, in the sense that subjectivity has in us attained new levels of complexity and self-organization. For Bookchin then, harmony with the natural environment is achieved not by a simple identification with Nature, such as deep ecologists prescribe, nor merely by a resolution of dualistic opposites - putting mind back into matter - as ecofeminists recommend. From his evolutionary point of view, we achieve harmony with nature, and save the planet, by allowing our own nature the freedom to unfold in its own essential way. Since our nature was formed in a thoroughly ecological system, and since the telos of such a system is the continual elaboration of greater complexity and further diversity, this is also the telos of our nature. We can accordingly only flourish in a society which preserves or recreates, or even enhances, at both social and biological levels, the ecological dynamic of our original matrix. Social relations as well as relations with the natural environment will have to be ecological, and therefore nonhierarchical, if we are to continue to evolve more complex and diverse forms of subjectivity or mentality. Our own self-realization, as individuals, and the further evolution of humanity, thus in fact call for the very kind of nonhierarchical society which, by eliminating psychologies of domination, ensures that our relations with the natural world are reciprocal and benign.

5 Foundations of the ecological view

The intuition of ecological interconnectedness has been epistemologically grounded and philosophically elaborated in ways beyond those already canvassed. For some authors any attempt to provide a theoretical foundation for this intuition is seen as misguided, since a sense of ecological interconnectedness is, according to them, properly derived from direct experience of nature in the field. Other authors appeal for justification to certain ’minority traditions’ within Western philosophy, such as pantheism, Romanticism, the monism of Spinoza or the process philosophy of Alfred North Whitehead. Eastern traditions, such as Daoism and Buddhism, and the spiritual traditions of indigenous peoples, are also invoked. Developments in disciplines other than philosophy, including the ’new physics’ (Capra 1983; Bohm 1980), systems theory (Bateson 1979; Lovelock 1979), biology (Maturana and Varela 1988) and cultural studies (Roszak 1973; Berman 1981) are cited by yet other authors. In all these areas, traditional assumptions about nature are being overturned and reorganized along more holistic or relational lines. Naess’ reminder that many different traditions and theories can provide the starting point for an ecological view of the world can be considered an essential aspect of the ecophilosophical project. His invitation to people to construct their own ’ecosophies’, drawing on direct experience and philosophical ideas that are familiar and congenial to them, implies that premises couched in terms as different as mythology, religion, science and mathematics may yet lead to conclusions convergent in relevant respects. Commitment to an ecological worldview, then, is not inconsistent with a high degree of epistemological pluralism and a rich diversity of cultural expression.

The idea that everything to a certain extent shares the fate of everything else is in fact the spiritual axiom of many pre-modern and non-Western societies. It may have been the rejection of this idea, in favour of the idea of division or separation, that helped to bring about the estrangement between Western philosophy and spirituality in the modern period. Perhaps - though some ecophilosophers would disagree - ecophilosophy represents a first step toward the reunion of these two pathways to understanding.

Ecology

Philosophers of science have paid relatively little attention to ecology (compared to other areas of biology like evolution and genetics), but ecology poses many interesting foundational and methodological problems. For example, the problems of clarifying the differences and causal connections between the various levels of the ecological hierarchy (organism, population, community, ecosystem…); the issue of how central evolutionary biology is to ecology; long-standing issues concerning the extent to which the domain of ecology is more law-governed or more a matter of historical contingency, and the related question of whether ecologists should rely more on laboratory/manipulative versus field/comparative methods of investigation.

1 The ecological hierarchy

Ecology is most often characterized as the study of the ’distribution and abundance of organisms’. For example, ecologists ask, what biotic factors (for example, predation, interspecific competition for resources) and/or abiotic factors (for example, climate) are responsible for the presence or absence of a species in a particular location, or for the diversity of species in a particular area? More specifically (to pose a few famous ecological questions), why are there so many different species on the face of the earth? Are there just as many species as there are niches (and what are ’niches’, anyway)? Why are there so many different species of plankton in a lake? Why are big, fierce animals rare?

Ecology is also characterized in terms of the hierarchy of entities that constitute its domain: organisms, populations (for example, the population of a particular species of bass in a lake), communities (for example, the interacting populations of bass, minnows and plankton in a lake), ecosystems (for example, the lake, including the bass, minnows and plankton), … the biosphere. (For the sake of comparison or contrast, the genetic/evolutionary hierarchy consists of genes, organisms, populations, species, genera, families, orders, classes … kingdoms.)

The ecological hierarchy imposes or affords two directions of causal analysis for each level. Thus, for example, ecology includes the study of changes in population size as influenced by traits of the organisms that compose the populations (’upward’ causation, in the sense of ’up’ the hierarchy), and the study of changes in population size in the context of the communities to which the populations belong (’downward’ causation). Ecologists study changes in community structure as influenced by the populations that compose the communities, and in the context of the ecosystems to which the communities belong. And so on. Among the most basic foundational issues that arise in ecology are the problems of clarifying the differences and causal connections between the different levels of the ecological hierarchy.

The diversity of spatial and temporal scales associated with the variety of ecological entities and processes is also an important consideration in many of the foundational and methodological issues that arise in ecology. Consider for instance the difficulty in characterizing the nature of ’communities’ - a maple-birch forest together with the deer that inhabit it may be considered one community, and the various interacting species of microorganisms that inhabit the gut of any one of those deer may be considered another community. To make matters more difficult, the species’ composition of a community may change over time as new species colonize the area in question and outcompete other species, and so on. At what point do we say that one community has been replaced by another?

2 Superorganisms

The upper levels of the ecological hierarchy have from time to time been conceived quite holistically, even as higher level organisms or ’superorganisms’. For instance, just as organisms of a particular species undergo a fairly regular sequence of developmental stages to adulthood, so too the species’ composition of a disturbed area has been thought to undergo a fairly regular sequence of ’successional’ stages back to the ‘mature’ state (for example, from the weedy annuals that first colonize a forest clearing, to the perennial herbs, to the shrubs, and ultimately to the trees that reconstitute the mature forest). Just as individual organisms display self-regulatory abilities (like the ability to maintain body temperature within a narrow range), so too populations, communities and ecosystems have been conceived as having self regulatory properties (like the ability of a population to regulate its size). Just as organisms of different species have distinctive metabolisms, so too different communities and ecosystems have distinctively different energy flows and nutrient cycles. Still more analogies have been pursued.

The superorganism concept was also motivated by methodological considerations. Ecology emerged as a self-conscious discipline in the early twentieth century when the methodological model for biology was experimental physiology, with its emphasis on the repeatable, the manipulable and the verifiable. This was considered the best antidote to excessive interest in evolution, which seemed bound-up with the historically unique, the nonmanipulable and the nonrecoverable. Early ecologists advocated the investigation of superorganisms in the manner in which experimental physiologists investigated organisms.

That is not to say that the superorganism concept is, or was, inherently anti-evolutionary. It has played an important role in 'group selection' theories (see Evolution, theory of; Sociobiology). For example, just as Darwinians have traditionally explained the prevalence of a type of organism in terms of natural selection for organisms of that type, so too some ecologists have explained the prevalence of some types of populations, communities and ecosystems in terms of the selective persistence of systems of those types. Superorganismal, group-selectionist concepts in ecology have been the target of considerable criticism from some evolutionary biologists, who argue that the concepts reflect a lack of understanding of evolution. However, these issues have been a fruitful source of discussion concerning the conceptual relationships of ecology to evolutionary biology (more about the connections between ecology and evolutionary biology later).

Many who have rejected superorganism concepts in ecology have nonetheless also rejected the idea that the higher level entities are merely interacting collections of the lower level components. They have held instead that the lower level components interact in such a way as to contribute to the integrity of the upper level entity. So for example, communities and ecosystems are understood by many to be integrated into food webs, which are in turn structured largely by predator-prey relations and interspecific competition for available prey/resources. This integrity has been characterized most generally as 'stability'. But this stability has proved difficult to characterize in a general way. Numerous variants of the concept have been elaborated: neighbourhood stability, global stability, dynamic stability, bounded stability, cyclic stability, trajectory stability, resistance, resiliency, constancy, elasticity, persistence, inertia, and more. Compounding the difficulty of specifying the nature of the integrity of higher level ecological entities is the scale - temporal and spatial - at which, and during which, the supposed stability is maintained.

3 Methodological issues

Proponents of the importance of evolutionary thinking in ecology have emphasized the role of natural selection in contributing to community and ecosystem integrity and stability. That is, to the extent that natural selection results in the mutual adaptation of the member species of a community, the community becomes a more integrated and stable whole. Arguments for the importance of evolutionary thinking in ecology have hinged on several issues, one of which concerns 'evolutionary time' versus 'ecological time'. Ecological time is often considered much shorter - too short for ecological processes to be influenced by evolutionary changes. Proponents of the importance of evolutionary thinking in ecology have challenged the distinction, arguing, for example, that evolution by natural selection occurs in a short enough time period to have a significant effect on the outcome of an ecological process. Consider for instance an ecological process like interspecific competition for resources. One possible outcome would be extirpation of one of the species from the area - a purely ecological phenomenon. But this is not the only possible outcome: one of the species could evolve in a direction that allows its members to make use of a resource not utilized by the other species. In this case, evolution would allow both species to coexist within a community.

The connections between ecology and economics may be as significant as the connections between ecology and evolutionary biology. Those connections are well evidenced by the importance within ecology of such concepts as resource, competition, consumer, producer, productivity, efficiency, energy budget, guild, and so on.

One of the major conceptual divides in ecology has been between those who view upper level entities of the ecological hierarchy as real entities having some characterizable integrity, and those who view the upper levels more as combinations of populations that coincidentally migrated to the same area and that coincidentally have the same range of environmental tolerances. Of course, this is a continuum, not a strict dichotomy of outlooks. Not only might any particular community lie between the extremes, but some communities might lie more towards one end of the spectrum, while other communities lie towards the other end. But many ecologists have pursued (and continue to pursue) the extremes.

Associated with this difference in perspective are other conceptual and methodological differences. Proponents of the more holistic viewpoint have tended to emphasize and focus on optimal equilibrium states in which higher level entities persist, and/or towards which they develop, and/or towards which they return when disturbed. Proponents of equilibrium viewpoints tend to belittle the importance of historical contingency, inasmuch as equilibrium states can be reached by different routes. Proponents of the alternative viewpoint tend to question the reality of equilibrium states, and stress the importance of historical contingencies. Although, again, this is a continuum of perspectives, not a strict dichotomy. And once again, the temporal and spatial scale of the investigation is relevant to the apparent importance of historical accident. While ecology distanced itself from history in its early days, and while leading ecologists continued to stress the differences between ecology and the historical sciences through the 1970s, there are now calls for a ’new ecology’ that takes historical contingency more seriously.

Discussions of the merits and implications of historical contingency versus equilibrium approaches often involve discussions of the predictiveness and nomic status of ecological theory. That is, to the extent that historical contingency prevails, it has been suggested, ecological theory will be less predictive and less law-like. Equilibrium theories are not the only way to bring predictiveness and law-like order to ecology; but they have long been held as the best hope. After all, equilibrium points are by definition predictable/inevitable as long as specifiable ’disturbing’ conditions do not obtain. Equilibrium specifications thus have just the right form for *ceteris paribus* laws.

A re-evaluation of the importance of historical contingency is also occurring in evolutionary biology. In ecology, as in evolutionary biology, concerns about history have led to discussions of methodology, and to criticism of the idea that the only proper methodological models are laboratory-based sciences such as particle physics and molecular biology. While ecology aligned itself methodologically with laboratory experimental physiology in its early days, it has recently been suggested that it might as well or better model itself on historical disciplines like astronomy and geology (see Geology, philosophy of). A wide range of experimental methodologies, from laboratory to field, and from manipulative to comparative, is employed in such disciplines and seems to have an important place in ecology as well.

Economics and ethics

Unlike many other sciences, economics is linked both to ethics and to the theory of rationality. Although many economists regard economics as a 'positive' science of one sort of social phenomena, economics is built around a normative theory of rationality, and has a special relevance to policy making and the criticism of social institutions. Economics complements and intersects with moral philosophy in both the concepts it has constructed and in its treatment of normative problems.

Fundamental to modern economics is its conception of human beings as rational agents, whose choices are determined by complete and transitive preferences. Although economists stress the usefulness of this notion of rationality in explaining human behaviour, rationality is clearly also a normative notion. The mathematical tools economists have developed to represent and study the implications of rational action in collective and interactive contexts are thus of immediate relevance to moral philosophers.

Also of interest to moral philosophy is the problematic attempt in welfare economics to fashion a normative theory of economic institutions and policies around the goal of helping people satisfy their subjective preferences. This project relies, controversially, on equating people's wellbeing with the degree of satisfaction of their subjective preferences; an individual's 'utility' on this view is no more than an index of how well their subjective preferences are satisfied. Furthermore, since most welfare economists assume that there is no meaningful way to compare degrees of preference satisfaction across people, the project also requires a scheme for weighing the effectiveness of alternative economic arrangements in satisfying preferences without weighing the comparative satisfaction levels of different individuals. Central to the project is Pareto optimality - the notion of an 'efficient' arrangement as one in which no individual can achieve higher preference satisfaction without someone else undergoing a reduction in their satisfaction level.

Economic policies and institutions can be appraised in terms of a variety of values other than efficiency. Notable both in historical and contemporary discussions are the values of liberty, justice and equality. Since a large part of economics is carried out with a view to its possible application to policy, ethics has a significant part to play in economics. By the same token, economics may be of great importance to ethics, both through its exploration of consequences and through the development of mathematical and conceptual tools.

1 Rationality

At the foundation of both positive and normative economics lies a normative theory of individual rationality (see Rational choice theory). The theory is very thin, because it raises no questions about the rationality of ultimate ends and few questions about the rationality of beliefs. The standard view of rationality concerns only the internal completeness and consistency of an individual's preferences and the connection between preference and choice. In 'revealed-preference theory' preferences are derived from choices, and rationality is in effect taken to be a condition on choices (actions) only. In the standard theory of rationality (and implicitly in revealed-preference theory, too), preferences are subjective states that lead to actions.

An agent *A* chooses (acts) rationally if *A*'s preferences are rational, and *A* never prefers an available option to the option chosen. *A*'s preferences are rational only if they are complete and transitive. *A*'s preferences are transitive if and only if, for all options *x*, *y*, and *z*, if *A* prefers *x* to *y* and *y* to *z*, then *A* prefers *x* to *z*. The same stands where *A* is indifferent. Transitivity is a plausible, although not completely uncontroversial, requirement of rationality. *A*'s preferences are complete if, for all options *x* and *y*, either *A* prefers *x* to *y*, or *A* prefers *y* to *x*, or *A* is indifferent between *x* and *y*. If *A*'s preferences are complete, then *A* is never unable to rank *x* and *y*. It is questionable whether completeness is a condition of rationality.

If an agent's preferences are rational, one can assign numbers to the objects of preference. These numbers, which are arbitrary apart from their order, merely indicate preference ranking. They are 'ordinal utilities', and the theory of rationality may be re-stated: agents are rational if and only if their preferences may be represented by ordinal utility functions, and their choices maximize utility. (Representation by a continuous utility function presupposes an additional technical condition.) One should avoid saying that they act 'in order to maximize utility'. In contemporary economic theory, utility is merely an index or indicator. It is not a substantive aim or an object of

preference. One cannot sensibly pursue utility or take more or less utility in exchange for more or less of some genuine object of preference. Maximizing utility is just doing what one most prefers to do.

This standard theory of rationality is silent concerning what to do in circumstances of risk or uncertainty. Someone who prefers $10 to $5 but who prefers a gamble with a $5 prize to an identical gamble with a $10 prize violates none of the axioms of the standard theory (see Risk). To extend the standard theory requires (apart from additional technical conditions) one further substantive axiom, the so-called 'independence condition' or 'sure-thing principle'. This condition says that when an individual faces a choice between two bets that are identical except for one prize, then they will prefer the bet with the preferred prize. When one's preferences satisfy this additional independence condition, then they can be represented by an 'expected utility function'. Such functions have three important features. First, the expected utility of a lottery, $U(L)$, that pays off R with probability p and S with probability $(1-p)$ is $pU(R)+(1-p)U(S)$. Second, if U and U' are expected utility functions representing the preferences of an agent, then $U'=aU+b$, where a is a real number greater than zero and b is any real number. Expected utility functions are thus said to be 'unique up to a positive affine transformation'. Third, the requirement that subjective degrees of belief conform to the axioms of the probability calculus is implicit in the application of expected utility theory in conditions of uncertainty. Hence expected utility theory also contains a thin theory of rational belief. Expected utilities, like ordinal utilities, only provide information concerning preference and are not themselves goals or objects of preference. In expected utility theory, as in ordinal utility theory, choice is determined by preference.

The standard views of rationality and the theorems that permit their mathematical representation provide a framework in which to pose questions about the relations between morality and rationality. Their importance to moral philosophy depends in addition on the links between this view of rationality and a particular view of welfare.

2 Utility theory and welfare

All plausible moral views assign an important place to individual wellbeing. This is most obviously true of utilitarianism, which takes morality as maximizing some function of the welfare of individual members of society (see Utilitarianism §§1-3). Non-utilitarian views that emphasize notions of rights, fairness and justice also need a conception of human wellbeing. These views not only recognize the virtue of benevolence, which requires some notion of human good, but even their core notions make reference to wellbeing. Thus, for example, justice is understood in terms of treating the interests of different persons properly, and acting rightly often involves avoiding harm to other individuals. Notions of harm and of interest are plainly connected to notions of human wellbeing.

Given the commitments of economists to utility theory in explaining human choices, it is natural that they would look also to levels of utility or of preference satisfaction as the fundamental measure of human wellbeing for evaluative purposes. And indeed it is easy to reason as follows. Rational people have complete and transitive preference rankings and choose from among the available alternatives what they most prefer. Rational people also choose from the available options whatever they believe to be best. If one assumes in addition (as is common in positive economics) that individuals have correct beliefs and that they are self-interested, then it follows that (among the available options) what rational people most prefer is what rational people choose, which is the same thing as what is best for them. In other words, wellbeing is the satisfaction of preference.

Philosophers are less happy than economists with the idealization involved in assuming correct beliefs, and they are less convinced that people are always self-interested. Hence, they generally reject a view of welfare as the satisfaction of actual preferences. A view of welfare as the satisfaction of 'informed' and self-interested preferences is however common in contemporary philosophy and suffices to make the tools and explorations of economists relevant to philosophical concerns (see Welfare §1).

As both economists and philosophers have noticed, preference-satisfaction theories of wellbeing are problematic, even if one insists that the preferences be informed and self-directed. For preferences that are not based on indisputably false beliefs may nevertheless be based on highly contestable beliefs. Even if the preferences of people who beg for money to make a sacrifice to their god are well-informed, others may question whether satisfying them will make these people better off. If the notion of individual wellbeing is to be employed in

weighing the strength of claims for social provision, it must permit reasoned social agreement on basic components of wellbeing and on the relative 'urgency' of claims to different goods (Scanlon 1975). One might acknowledge a moral obligation to feed such people, but not to finance their worship.

There are other reasons, too, to question whether the conception of wellbeing as the satisfaction of preferences is suitable for assessing claims to scarce resources. For example, a person who has cultivated a taste for exotic foods may be miserable without them and, in one sense, worse off than someone in similar circumstances who delights in junk food. But one may question whether social policy should be responsive to such preferences. Similarly, it is questionable whether satisfying racist, sadistic and other antisocial preferences should count as contributing to individual wellbeing. Also of concern are 'adaptive preferences' and the effects of culture on preferences (Elster 1983; Sen 1987). For example, women who are systematically denied roles in public life, or equal shares of consumption goods, may learn not to want what they have not got. Their utility may be reasonably high, but objectively their level of wellbeing may be low.

Despite these difficulties, most economists prefer to cling to a preference-satisfaction view as a reasonable approximation. Philosophical proponents of these views (for example, Griffin 1986) have worked hard to deflect some of the objections and have defended the view that wellbeing is the satisfaction of 'informed' or 'rational' preferences. The commitment most economists have to a preference-satisfaction view derives from the links between a preference-satisfaction view of welfare and the explanatory uses of utility theory, and it is strengthened by the strong aversion many economists feel to anything that smacks of paternalism. Even though recognizing that individuals may be wrong about what is good for them does not imply that one should support paternalistic policies; it permits the question of paternalism to come up.

3 Alternative views of wellbeing

On the other hand, the difficulties with a subjective preference-satisfaction view of wellbeing have led many philosophers and a few economists to propose different conceptions of wellbeing: traditional hedonistic views and hybrids such as Sidgwick's (1901) view that certain mental states are intrinsically good yet are good because they are intrinsically desired, 'perfectionist' views in which the desires that count and their weight depend on the objective value of their objects (Griffin 1986; Parfit 1984; Raz 1986), Rawls' 'primary goods' (1971) and Amartya Sen's 'capabilities' (1987, 1992).

In Sen's view, a capability is the ability to achieve a certain sort of 'functioning' - literacy is a capability; reading is a functioning. People may value capabilities for their own sake as well as for the functionings they permit - you are glad to know you can walk around even if you are inclined to stay put. In Sen's view, preference satisfaction is too crude and too insensitive to the variety of values to serve as the basis for social evaluation. Rawls' primary-goods approach also fails to include a wide-enough range of relevant 'capabilities'. In focusing on primary social goods, Sen argues that it leaves out more internal features of persons' circumstances, such as physical handicaps, which may profoundly affect wellbeing. Rawls' account also may not work well for comparing the wellbeing of persons who are much above the minimum.

Sen's alternative is to define wellbeing in terms of the set of functionings a person achieves. Being well nourished is an example of a functioning whose achievement may be impaired either by internal obstacles (such as a digestive disorder) or external ones (a lack of money to buy food). Functionings are of course a vector (being well nourished, reading books, sleeping well) and combining them into a measure of wellbeing requires settling on the relative weight to be given to different capabilities and functionings. Obviously the problems of weighing different capabilities and functionings are serious. But even if they are insuperable and it turns out that focusing on capabilities and functionings sometimes leaves one unable to rank social alternatives, such an approach still leads one to focus on the morally relevant features of social alternatives. Particularly in the context of poor people and poor countries, measuring the extent of certain basic capabilities, like literacy or health-related capabilities, may be an effective way of gauging levels of wellbeing.

One important advantage of more objective approaches is that they avoid the problems of interpersonal comparison that derive from identifying wellbeing and utility (construed as an index of preference satisfaction). Formerly, economists such as Pigou (1920) argued that overall welfare would be maximized by equalizing incomes as much as was consistent with retaining incentives to produce. Citing diminishing marginal utility of

income, they maintained (not implausibly), that $100 contributes less to the wellbeing of someone with an income of $50,000 than to the wellbeing of someone with an income of $5,000. Other things being equal, a more equal distribution of income would increase total welfare.

This argument supposes that one can compare the contributions income makes to the wellbeing of different people. Once one takes seriously the preference-satisfaction view of wellbeing, these comparisons become problematic. Lionel Robbins (1932) argued compellingly that since preference rankings are entirely subjective and introspective, there is no way to compare where *A* is in *A*'s preference ranking with where *B* is in *B*'s ranking. The fact that people nevertheless make interpersonal comparisons of wellbeing depends, Robbins argues, on the value judgment that the preferences of people in similar circumstances are similarly satisfied. (One might instead question whether these comparisons of wellbeing are comparisons of preference satisfaction.)

Robbins' argument did not convince everyone. One approach has been to build up interpersonal welfare judgments from individual judgments of the form: 'I would prefer to be person *P* with consumption bundle *x* than *Q* with consumption bundle *y*' (see Kolm 1972 and Harsanyi 1977). If there is widespread agreement among individuals on such extended preferences, they can be used to construct interpersonally comparable welfare measures. Alternatively such 'extended preferences' may summarize what a perfected psychological theory would say about the relationship between the causal factors that lead people to have the preferences they have and the states of the world that satisfy preferences.

Although preference-satisfaction views of welfare do permit one to make use of the technical apparatus economists have developed, one should note the many problematic features of such views. The identification of wellbeing with the satisfaction of preferences is questionable in itself. It gives rise to serious problems of interpersonal comparisons. It is biased by adaptive preferences, and it fails to link up with the normative terms of policy debate.

4 Efficiency and Pareto optimality

Economists have given the common-sense notion of 'efficiency' a precise technical meaning: adopt the metric of utility (preference satisfaction) to measure a person's wellbeing. Consider some allocation of resources which yields a certain distribution of utility. A different allocation is a 'Pareto improvement' if and only if it makes at least one person better off (in terms of preference satisfaction) and makes no one worse off. An allocation is 'efficient' or 'Pareto optimal' if no other allocation is a Pareto improvement compared to it. In other words, in a Pareto optimal allocation, every alternative that satisfies someone's preferences better leads to someone else's preferences being less well satisfied. The great attraction of this notion for economists is that it permits a partial ranking of resource allocations or of social states which is responsive to individual preferences without employing any interpersonal comparisons of utility.

If one is minimally benevolent and favours making people better off, then, other things being equal, one should favour prospects that are better for someone and worse for no one. If in addition one identifies being better off with having a higher utility, then (other things being equal) one will endorse Pareto improvements and Pareto optimal allocations. Moreover, one can offer an argument in terms of these concepts for regarding a perfectly competitive equilibrium as a sort of moral ideal, other things being equal. What economists call 'the first welfare theorem' shows that competitive equilibria under certain idealized conditions (no externalities, no public goods, no informational limits, and so on) are Pareto efficient. Minimal benevolence then implies that competitive equilibria are (other things being equal) morally good economic states, and that market failures are bad. Furthermore, the 'second welfare theorem' shows that an efficient economic outcome producing any desired distribution of welfare can be attained by the workings of a competitive market, given the right initial distribution of endowments to agents. So with no ethical premise more controversial than minimal beneficence, albeit with a controversial conception of individual wellbeing, economists can offer moral evaluations along one significant dimension.

However, the Pareto principle may be unappealing when it involves honouring people's intrusive preferences regarding others' consumption patterns or levels of wellbeing. Moreover, it has been shown that the Pareto principle is inconsistent with the conjunction of individual and collective rationality in conditions of uncertainty (Seidenfeld *et al.* 1989). The problem lies in the fact that unanimity in individual rankings may rest on disagreements in subjective probability judgments and disagreements in preferences among options involving no uncertainty. Should unanimity in individual preference for *A* over *B* require that *A* be judged better, if the

unanimity depends on disagreements in values and probability judgments? Quite apart from these problems, the Pareto principle has very limited applicability, since economic changes usually involve winners and losers. Economists have been reluctant to accept these severe limitations and have struggled for many years over the issue of whether, without invoking interpersonal utility comparisons, some device could be found that would permit judgments in cases involving trade-offs among individuals. The hope was that one could find a way to endorse ‘potential Pareto improvements’, in which the gains to the winners were sufficient to compensate the losers in utility terms, without actually making the compensation (Hicks 1939; Kaldor 1939). The conclusion has been that no such blanket endorsement is possible, partly owing to technical failings in the proposed devices for identifying ‘improvements’, but more fundamentally because there simply is no way to judge changes that affect distributions while remaining neutral on distributive questions (Little 1957; Streeten 1953; Samuelson 1950). But to stop here would leave welfare economists with little to say, and practical applications of welfare economics in the form of cost-benefit analysis need to go on (see Pareto principle).

The difficulties seem to have been dealt with in two ways. One is by increasing modesty: one cannot always endorse potential Pareto improvements, but at least economists can identify them and leave the endorsing to politicians. Second, it seems that welfare economists have moved implicitly towards reuniting considerations of efficiency and equity. Blanket endorsements of potential Pareto improvements are unjustifiable, but since there are various theoretical ways to adjust such measures for equity concerns, one can suggest that equity-adjusted potential Pareto improvements can consistently be endorsed. (Stimulated partly by an interest in making inequality comparisons and equity judgments more precise, economists have devoted extensive energy to developing a variety of statistical techniques for measuring and describing inequality (Sen 1992).) Economists remain queasy about the final step of actually endorsing any one way of adjusting for equity concerns.

5 Economics and ‘moral mathematics’

There are currently many areas in which the tools and theories of economists have contributed to moral philosophy. The two areas of economics that have been of the most immediate relevance to moral philosophy have been social choice theory and game theory (see Social choice theory §3; Rational choice theory §§2-3). Economists and philosophers have used social choice theory and game theory mainly to investigate questions concerning the aggregation of individual preferences and judgments and concerning justice in social coordination and bargaining. But the tools of economics may apply to a much wider range of ethical issues. For example, there has been an energetic debate concerning conceptions of equality that has depended on formal concepts and arguments developed by economists (see Equality). When two individuals do not have exactly the same bundles of commodities, what could economic equality mean? One answer is ‘welfarist’: economic equality is equality of preference satisfaction. But economists seek to avoid making interpersonal utility comparisons, and it is questionable whether egalitarians should be concerned to equalize welfare. Another way to give sense to the notion of equality is to suppose that individuals acquired their different commodity bundles by means of voluntary exchanges beginning from a situation in which all had identical bundles (Dworkin 1981). In that case the allocation will be ‘envy-free’ in the sense that no one will prefer the commodity bundle of anyone else. It is then possible to investigate formally a number of questions: when will envy-free allocations exist? When will they be Pareto optimal? What sorts of events will upset or preserve the envy-freeness of a distribution? Is there any alternative formal characterization of equality? Here is an area in which inquiries of moral philosophers and economists are closely interwoven. There are others, too, ranging from John Roemer’s (1988) formal explorations into concepts of exploitation to recent work attempting to give a formal characterization of freedom.

6 Conclusion

Economists and moral philosophers share interests in rationality and in the evaluation and criticism of social institutions. Although the theoretical precommitments and starting points of scholars trained in these disciplines are often different, the two subjects have a great deal to offer one another. To the extent that moral philosophers want to bring their work to bear on the criticism and reform of social institutions, they have much to learn from economists, who have long been concerned with working out the consequences of alternative policies and with finding operational measures of theoretical concepts. Economists offer moral philosophers a range of powerful tools. At the same time, economists concerned with evaluating institutions and policies can hardly avoid a concern with ethics.

Economics, philosophy of

People have thought about economics for as long as they have thought about how to manage their households, indeed Aristotle compared the study of the economic affairs of a city to the study of the management of a household. During the two millennia between Aristotle and Adam Smith, one finds reflections concerning economic problems mainly in the context of discussions of moral or policy questions. For example, scholastic philosophers commented on money and interest in inquiries concerning the justice of 'usury' (charging interest on money loans), and in the seventeenth century there was a great deal of discussion of policy concerning foreign trade. Economics only emerged as a distinct field of study with the bold eighteenth-century idea that there were 'economies' - that is autonomous law-governed systems of human interaction involving production, distribution and exchange. This view was already well developed in Adam Smith's Wealth of Nations, from which much of economics derives.

Economics is of philosophical interest in three main regards: it raises moral questions concerning welfare, justice and freedom; it raises foundational questions concerning the nature of rationality; and it raises methodological or epistemological questions concerning the character and possibility of knowledge of social phenomena. The fundamental theory of standard orthodox economics is of particular epistemological interest because of its resemblance to theories in the natural sciences coupled with its uneven empirical performance.

More than 150 years ago John Stuart Mill confronted the problem of how to reconcile his high regard for economics (despite its empirical adequacies) with his commitment to empiricism. His solution, which was accepted by most economists until the 1930s, held that the basic principles of economics are well established by introspection or everyday experience. One can thus justifiably have confidence in economics, despite the inexactness of its implications, which is only to be expected, since economics deals only with the most important determinants of economic phenomena.

In the 1930s Mill's views were rejected as too dogmatic and insufficiently empirical. But the views that succeeded Mill's during the generation after the Second World War, most notably the position of Milton Friedman and views deriving from the work of Karl Popper and Imre Lakatos, were less able to deal satisfactorily with the empirical inadequacies of economic theories than were Mill's. Since the mid 1980s there have been several new approaches, ranging from Donald McCloskey's rejection of methodological assessment at one extreme to Alexander Rosenberg's conclusion that economics cannot be a successful empirical science at the other.

1 What is economics?

Contemporary economics is divided into many schools and branches. The main 'orthodox', 'neoclassical', or 'neo-Walrasian' school models economic outcomes as equilibria in which individuals have done as well for themselves as they could given their preferences and the constraints on their choices. Common to all branches of orthodox economics are standard assumptions concerning technological possibilities and individual choice. Production is subject to diminishing returns to additional units of any given input, other inputs held constant, and is assumed not to show increasing returns to scale. The rational choices of individual agents are constrained by their initial endowment with resources and goods and by the technological possibilities. Agents are rational in the sense that their choices are determined by their preferences, which are complete and transitive. An agent's preferences are complete if they can rank all alternatives. An agent's preferences are transitive if for all alternatives *x*, *y* and *z*, they prefer *x* to *z*, whenever they prefer *x* to *y* and *y* to *z* (and similarly for indifference). Agents are typically assumed to want more consumption or leisure for their households and greater net returns for their firms. In competitive markets it is assumed that firms and individuals cannot influence prices, but economists and game theorists are also interested in strategic interactions, in which the rational choices of separate individuals are interdependent.

Orthodox economics has four main branches and many sub-specialities. The view of economic phenomena as equilibria resulting from constrained rational individual choice has a greater prominence in some branches and subspecialities than in others. It is central in the most theoretical branch, which consists of microeconomics, general equilibrium theory and game theory. Econometrics, in contrast, is as much statistics as economics. It uses data and statistical techniques to determine the values of parameters and to test specific models. Macroeconomics,

the third branch, is concerned with whole economies and particularly with the causes of the business cycle and economic growth. In John Maynard Keynes' *General Theory* (1936) its links with individual choice are tenuous. Contemporary economists in contrast have defended alternative macroeconomic theories in which the view of economic phenomena as equilibria resulting from constrained rational choices is central. The fourth branch, consisting of orthodox work in 'applied economics' (which is what most economists do), is consistent with the general theoretical picture of economic equilibrium, but applied theories make further simplifications to facilitate application. Within particular sub-specialities, such as international trade theory, labour economics or financial economics, one may find work lying along all of the four main branches.

There are also many other schools of economics. Austrian economists accept orthodox views of choices and constraints, but they emphasize uncertainty and question whether one should regard outcomes as equilibria. Institutionalist economists question the value of abstract general theorizing. They emphasize the importance of generalizations concerning norms and behaviour within particular institutions. Applied work in orthodox economics is sometimes very similar to applied institutionalist economics. Marxian economists traditionally articulated and developed Karl Marx's economic theories, but recently many Marxian economists have revised traditional Marxian concepts and themes with tools borrowed from orthodox economic theory. There are also socioeconomists, behavioural economists, chaos theorists, post-Keynesians, and neo-Ricardians. Within orthodox economics itself, there are also many different schools or approaches, such as agency theorists, the Chicago school, constitutional political economy, new institutional economics, and public choice theory. Economics is not one homogeneous enterprise. This entry will focus on neoclassical economic theory because the orthodox neoclassical school is the best known and most influential and because its central theory has attracted the most philosophical attention.

2 Why is economics of philosophical interest?

Economics has been of philosophical interest in three main regards. First, it raises moral questions concerning freedom, social welfare and justice. Although economists often deny that their theories have ethical content, they are ready with advice about how to make life better. Markets, which are the central institutions with which economics has traditionally been concerned, involve voluntary interactions, yet they are simultaneously mechanisms that regulate individual activities and allocate goods to people. They thus raise intricate moral questions concerning coercion, voluntary action, and social justice (see Economics and ethics). All of the leading figures in contemporary social and political philosophy comment on and are influenced by work in economics Hausman and McPherson (1996).

Second, contemporary theoretical economics is largely a theory of rational choice. This may seem surprising, since economics is supposed to be an explanatory and predictive science of the actual interactions among people rather than a normative discipline studying how people ought rationally to choose, but it is indeed a fact. This fact joins the interests of economists to the interests of those philosophers concerned with rational choice (see Rational choice theory; Social choice).

Third, economics raises important questions in philosophy of science. In part this is because all significant cognitive enterprises raise questions for epistemology or philosophy of science. But orthodox theory is of particular methodological interest for seven reasons.

Positive and normative. The extent to which economics appears to be permeated with normative concerns raises methodological questions about the relationships between a positive science (of 'what is') and a normative science (of 'what ought to be'). The standard view is that the positive science of economics, like engineering, helps policy-makers to choose the means to accomplish their ends, but it has no bearing on the choice of ends itself. This view is questionable, because economists have to interpret and articulate the incomplete specifications of goals and constraints provided by policy makers (see Value judgments in social science).

Reasons and causes. It is of philosophical interest that orthodox theoretical economics is as much a theory of rational choices as it is a theory that explains and predicts economic outcomes. Although economists are more interested in the aggregate results of individual choices than in the choices themselves, their theories offer both causal explanations for why individuals choose as they do and accounts of the reasons for their choices. Embedded within orthodox economics is a specific variant of 'folk psychology', and orthodox economics provides a specific

context in which to question whether folk-psychological explanations in terms of reasons can also be causal explanations (see Psychology, theories of; Explanation in history and social science).

Naturalism. Of all the social sciences, economics most closely resembles the natural sciences. Economic theories have been axiomatized, and essays and books of economics are full of theorems. Of all the social sciences, only economics boasts a Nobel Prize. Economics is thus a test case for those concerned with the extent of the similarities and differences between the natural and social sciences (see Naturalism in social science §2).

Abstraction and idealization. Economics raises questions concerning the legitimacy of severe abstraction and idealization. For example, economic models often stipulate that everyone is perfectly rational and has perfect information or that commodities are infinitely divisible. Such claims are exaggerations, and they are clearly false. Can good science make such false claims (see Scientific realism and social science)?

Ceteris paribus clauses. Because economists attempt to study economic phenomena as constituting a separate domain, influenced only by a small number of causal factors, the claims of economics are true only *ceteris paribus* - that is, they are true only if there are no interferences or disturbing causes. What are *ceteris paribus* clauses, and when if ever are they legitimate in science (see Social laws)?

Causation. Many important generalizations in economics make causal claims. For example, the law of demand asserts that a price increase will (*ceteris paribus*) diminish the quantity demanded. Yet economists are wary of causal language because of its suggestion that outcomes have single causes and because of difficulties in integrating talk of causation and talk of mutual determination. Econometricians have also been deeply concerned with the possibilities for determining causal relations from statistical evidence and with the relevance of causal relations to the possibility of consistent estimation of parameter values (see Causation §3).

Structure and strategy. During the past generation philosophers of science have been concerned to comprehend the larger theoretical structures that unify and guide research within particular research traditions or research programmes. Since orthodox economics is systematically unified, though not in quite the way that Kuhn (1970) or Lakatos (1970) discuss, it poses interesting puzzles about what guides research. Since the success of orthodox economics is controversial, this ‘research tradition’ also poses questions about how unified and constrained research ought to be.

These are the seven most significant philosophical issues concerning neoclassical economic theory, and many of these issues arise concerning all schools of economics.

3 Classic discussions of philosophical foundations

Explicit methodological reflection on economics dates back to the 1830s to the work of Nassau Senior (1836) and John Stuart Mill (1836). Their methodological reflections must be understood against the backdrop of the economic theory with which they were familiar. That theory (‘classical economics’) said comparatively little concerning the choices of consumers and supposed that people seek more wealth and are overly inclined to reproduce. With diminishing returns in agriculture and an increasing population, the rate of return in agriculture (and, given the mobility of capital, elsewhere) will diminish, and the ultimate result will be a stationary state in which profits are low, workers receive subsistence wages, and landlords receive large rents. On account of this view of the future, economics was called ‘the dismal science’. Classical economics, like contemporary theory, relied on bold simplifications and it had empirical difficulties. Although populations grew considerably, the rate of return in the nineteenth century did not fall sharply, and wages increased dramatically.

Mill was firmly committed to the economics of his day, yet he was a strict empiricist (see Mill, J.S.; Empiricism §5). Since economics faced such major empirical difficulties, it might appear that Mill would have to change his epistemology or disavow his economics. Call this conflict between empiricism and economics, which arises from the apparent disconfirmations of economics and the difficulty of testing it, ‘Mill’s problem’. Mill attempted to solve it by maintaining that the basic premises of economics are empirically well established by introspective psychology or by experimental testing of technical claims such as the law of diminishing returns. These well-supported premises state how specific causal factors operate. If the only causal factors influencing economic phenomena were those specified in these premises, then the predictions of economic theory would be correct. But economic phenomena depend on many causal factors that are left out of economic theories. Consequently, the

implications are inexact. They are always imprecise, and when the factors left out are of particular importance, the predictions of the theories may be completely mistaken. This inexactness explains why the implications of economic theories are so poorly confirmed, and consequently the problems do not show that there is anything mistaken in the fundamental generalizations of economics. In Mill's view, the empirical confirmation of economic theories is indirect and 'deductive'. It derives from the confirmation of their premises. The inductive method of 'specific experience' cannot be employed because of the multiplicity of causes. Furthermore, since there is no way to incorporate a much larger number of causal factors without destroying the 'separateness' of economics and subsuming it into a general social science, this inexactness is an inevitable feature of economics as a distinct discipline. Economics is unavoidably a science of 'tendencies' only.

Mill's view was tremendously influential until the 1930s, although there were always critics who argued for a more directly empirical approach to assessing economic theories. The most important methodological works of the late nineteenth century, J.E. Cairnes' *The Character and Logical Method of Political Economy* (1875) and John Neville Keynes' *The Scope and Method of Political Economy* (1891) defend Mill's view, and one can still find it clearly expressed in Lionel Robbins' classic *An Essay on the Nature and Significance of Economic Science* (1932). Some have also argued that Mill is, in fact, essentially right Hausman (1992, chaps 8, 12). But by the 1940s most of those writing on economic methodology had repudiated Mill's view of economics as a separate and inexact science justified by a deductive method.

Methodological challenges to Mill's view before the 1930s came mainly from those working outside the orthodox mainstream. The most important challenge came from the German Historical School in the nineteenth century and from the American Institutionalists in the twentieth century. These critics argued that theories should apply more directly to specific historical circumstances and should be tested more directly through these applications. Members of the German Historical School also questioned whether it is possible to separate a positive economic science from normative issues of policy making. Mill accepts the positive/normative division, though not in quite its modern form, and it is explicit in later followers such as J.N. Keynes. Members of the German Historical School wanted economic theorizing to be more explicitly normative and oriented toward specific historical circumstances and policy recommendations.

Although these objections did not shake the views on theory assessment accepted by mainstream economists, views which remained stable for the century after Mill, changes in philosophical conceptions did accompany the significant changes that occurred during that century in economic theory itself. Neoclassical economics, unlike its classical predecessor, focuses on individual choices, which unavoidably reflect subjective preferences and beliefs. This fact disturbed critics of neoclassical economics, such as Thorstein Veblen, who saw it as a departure from the general trend of science away from teleological concerns and towards objective causal relations (1898). Defenders such as Frank Knight, Ludwig von Mises and Lionel Robbins agreed that the role of subjective factors sets economics apart from the natural sciences. But they denied that the methodological distinctiveness of economics demonstrates any methodological error. Indeed von Mises and his followers saw this peculiarity of economics as a virtue that provides a special certainty to the conclusions of economics (1949). In their view (though not in the view of other so-called 'Austrian' economists such as Hayek), the conclusions of economics are beyond rational dispute, because they result from the privileged access people have to their preferences and beliefs or because they derive from the meaning of rationality (see Certainty).

The neoclassical focus on individual choice also led to a redefinition of the discipline. Mill and the classical economists had seen economics as concerned with specific causal factors - essentially acquisitive motives, diminishing returns, and the propensity to reproduce - which preponderate in a specific domain of social life (1836: 323). Robbins, in contrast, defined economics as 'the science which studies human behaviour as a relationship between ends and scarce means which have alternative uses' (1932: 15). In Robbins' view, economics is not concerned with production, consumption, distribution or exchange as such. It is instead concerned with an aspect of all human action. The causal factors with which economics is concerned - rational self-interest - have a role in all human affairs. This vision of economics has been vindicated to some extent by applications of economic models to matters such as decisions to marry Becker (1981) and by the development of game theory (see Decision and game theory). To regard the subject matter of economics as an aspect of all human action is nevertheless an exaggeration, since economists continue to focus on a particular domain of social phenomena and on causal factors - such as diminishing returns - that are of particular importance only in that domain.

The methodological reflections of Knight, Robbins, and the Austrians reinforced Mill's views of economics as an inexact science, whose conclusions are credible because they follow deductively from well-established premises. Yet this view of theory assessment in economics, which was virtually unchallenged within mainstream economics in 1930, was almost without defenders by the end of the 1950s. During this short period economists came to believe that Mill's view of confirmation was insufficiently empirical. Economics could be scientific only if its theories were subjected to empirical testing, and its theories could be rationally acceptable only if they passed these tests. It looks as if economists became familiar with the work of the logical positivists (see Logical positivism) and applied their views to economics. But there is little solid evidence that the methodological changes were the result of the influence of logical positivism. The general changes in intellectual climate that gave rise to logical positivism may have separately caused this revolution in economic methodology. Books by Lesley Fraser (1937), Terence Hutchison (1938) and Felix Kaufmann (1944) made the case for such a methodological reorientation. Hutchison's was the most influential of these books (probably because of Frank Knight's lengthy attack on Hutchison's views in the *Journal of Political Economy* (1940). Hutchison had studied in Germany and was familiar with the work of the logical positivists and of Karl Popper, and he complained that statements qualified with vague *ceteris paribus* clauses cannot be refuted.

Paul Samuelson's work on the theory of revealed preference (1938) was especially influential. Samuelson showed that if consumer choices in simplified models satisfy a consistency condition, then it is possible in principle to construct from the choices a preference ordering over commodity bundles. His work thus suggested that it might be possible to reformulate economic theory without relying on hard-to-test claims about subjective states of choosers. In teasing out the 'operationally significant' content of economics from its mentalistic formulation, one might be able to make economics conform to demanding empiricist strictures. Samuelson was himself more influenced by the work of scientists such as Gibbs and Bridgman than by the logical positivists, and his own view of methodology (1963), which essentially repudiates all generalizations that are not themselves separately and directly testable, is more extreme than are the views of the logical positivists.

Whatever the cause, Mill's views were eclipsed. Methodologists no longer defended them, although it is arguable that economists continued to rely on them in practice. But Mill's problem remained. Neoclassical economic theory, like its classical predecessor, is hard to test and often apparently disconfirmed. Unless one is prepared to reject the theory or to deny that theories ought to fit the data, one needs to provide some defence of the empirical credentials of economics.

4 Milton Friedman's views

Since the mid twentieth century a large literature devoted to economic methodology has emerged. That literature explores many methodological approaches and applies its conclusions to many schools and branches of economics. Most of the literature focuses on the fundamental theory of mainstream economics - the theory of the equilibria resulting from constrained rational individual choice. This section focuses on Milton Friedman's extremely influential views. Two particularly significant alternatives to Friedman not discussed here can be found in Machlup (1978) and Samuelson (1963).

In his 1953 essay, 'The Methodology of Positive Economics', Friedman argued that the only relevant test of an economic theory is its success in predicting the phenomena that economists are concerned with. He believes that standard microeconomic theories and the quantity theory of money pass such tests well. He responds to criticisms of theories that point out that they contain 'unrealistic assumptions' (such as the assumption that firms are profit maximizers) by arguing that the criticisms presuppose mistakenly that theories can be tested by their assumptions. In Friedman's view, Mill's problem evaporates as soon as one recognizes that scrutinizing the realism of assumptions is a methodological mistake.

Friedman begins his essay by distinguishing sharply between positive and normative economics (see Economics and Ethics §5). He dismisses the possibility of rational argument concerning values, but maintains that disagreements about economic policy result more from disagreements concerning the consequences of alternative policies than from disputes about values. The goal of positive economics is, in Friedman's view, exclusively predictive: 'The ultimate goal of a positive science is the development of a "theory" or ‘‘hypothesis" that yields valid and meaningful (i.e., not truistic) predictions about phenomena not yet observed' (1953: 7). Friedman thus defends an instrumentalist view of science. Note that 'predictions' here are simply implications of a theory whose

truth is not yet known.

Friedman’s central claim that the realism of ‘assumptions’ is irrelevant to the assessment of a theory does not follow from a standard instrumentalist perspective, in which the correctness or incorrectness of all the observable consequences of a theory bear on its acceptability. For the assumptions of economics (for example that firms maximize profits) are testable, and a standard instrumentalist would not dismiss apparent disconfirmations as irrelevant. To make sense of Friedman’s position, one must recognize that he rejects a standard instrumentalist concern with all the predictions of a theory. Friedman denies that the goal of economics is predictive success in general. The practical point of an economic theory is correct prediction only for ‘the phenomena it purports to explain’ (1953: 30). A good tool need not be an all-purpose tool. The fact that survey results are inconsistent with predictions derived from the hypothesis that firms are profit maximizers is irrelevant, because survey results are not among the phenomena that the theory of the firm is intended to explain.

From his thesis that the goal of economics is such ‘narrow’ predictive success, Friedman jumps to the conclusion that narrow predictive success is the only relevant test. Although tempting, this inference is a mistake. It is like arguing that the only relevant way to check a computer program is to run it and see whether it does what it is supposed to. If it is possible to tell for sure by running a program whether it will always do what it is supposed to, then there is indeed no point to studying the code (though studying the code might be cheaper and easier than investigating what happens when one runs the program). But with economic theories, as with complicated computer programs, one can only look at a small sample of their performance, and success in the sample is no guarantee of success in general. One cannot look and see how well the theory performs with respect to the full range of phenomena it was designed to account for. Indeed, the point of a theory is precisely to provide guidance when one does not yet know how the theory’s predictions come out. Just as one can assess computer programs by studying their code or examining how they work in uninteresting applications, so one can assess theories by examining their assumptions and attending to the success or failure of uninteresting predictions. Such scrutiny of the ‘realism of assumptions’ is of particular importance when extending a theory to new circumstances or when modifying a theory in the face of predictive failure.

Friedman’s narrow view of the goals of economics is also contestable. Even though economics has a crucial policy mission, many economists are concerned to explain economic phenomena, and many simply want to know the truth about various aspects of economies. Those economists obviously cannot accept Friedman’s view that the realism of assumptions does not matter. The argument above shows that economists who accept Friedman’s narrow view of the goals of economics cannot dismiss criticisms of the realism of assumptions either. Friedman does not solve Mill’s problem.

5 Popperian perspectives

A second modern approach to Mill’s problem derives from Karl Popper’s philosophy of science and is more critical of economics (see Popper, K. §§2-3). Popper defends a ‘falsificationist’ methodology. Scientists should formulate theories that are ‘logically falsifiable’ - that is, inconsistent with some possible observation reports. ‘All crows are black’ is logically falsifiable, since it is inconsistent with (and would be falsified by) an observation report of a red crow. Second, Popper maintains that scientists should subject theories to harsh tests and should be willing to reject them when they fail the tests. Third, scientists should regard theories as, at best, interesting conjectures. Passing a test does not confirm a theory or provide one with reason to believe it. All it does is to justify continuing to employ it (since it has not yet been falsified) and devoting increased efforts to attempting to falsify it (since it has thus far survived testing). Popper has also written in defence of what he calls ‘situational logic’ (which is basically rational choice theory) as the correct method for the social sciences. There appear to be serious tensions between Popper’s falsificationism and his defence of situational logic, and his discussion of situational logic has not been as influential as his falsificationism. For discussion of this aspect of Popperian economic methodology, see Hands (1985).

Given Popper’s philosophy of science, there seems little hope of solving Mill’s problem without rejecting contemporary economic theory and condemning its practitioners as behaving in scientifically illegitimate ways. For specific economic theories are rarely logically falsifiable. When they are, they are rarely subjected to tests, let alone harsh tests. When they fail the tests, they are rarely repudiated. Worst of all, economic theories, which have not even been well tested, are taken to be well-established, perhaps even unquestionable guides to policy, rather

than merely conjectures. Some critics of neoclassical economics have made these criticisms Eichner (1983). But most of those who have espoused Popper's philosophy of science have not repudiated mainstream economics and have not been harshly critical of its practitioners.

Mark Blaug (1992) and Terence Hutchison (1938), who are the most prominent Popperian methodologists, criticize particular features of economics, and they both call for more testing and a more critical attitude. But both understate the radicalism of Popper's views and take his message to be merely that scientists should be critical and concerned to test their theories. Blaug's and Hutchison's criticisms have sometimes been challenged on the grounds that economic theories cannot be tested, because of their *ceteris paribus* clauses and the many subsidiary assumptions required to derive testable implications Caldwell (1984). But this response ignores Popper's insistence that testing requires methodological decisions not to attribute failures of predictions to mistakes in subsidiary assumptions or to 'interferences'. For views of Popper's philosophy and its applicability to economics, see de Marchi (1988) and Caldwell (1991).

Applying Popper's views on falsification literally would be destructive. Not only neoclassical economics, but all known and probably all imaginable economic theories would be condemned as unscientific, and there would be no way to discriminate among economic theories. One major problem is that one cannot derive testable implications from theories by themselves. To derive testable implications, one also needs subsidiary assumptions or hypotheses concerning distributions, measurement devices, proxies for unmeasurable variables, the absence of various interferences, and so forth (see Duhem, P.; Quine, W.V. §1). These problems arise generally and Popper proposes that they be solved by a methodological decision to regard a failure of the deduced testable implication to be a failure of the theory. But in economics the subsidiary assumptions are extremely uncertain and in many cases known to be false. Making the methodological decision that Popper requires is unreasonable and would lead one to reject all economic theories.

Imre Lakatos (1970), who was for most of his philosophical career a follower of Popper, offers a broadly Popperian solution to this problem (see Lakatos, I.). Lakatos denies that one tests individual theories. When theories face empirical difficulties, as they always do, one attempts to modify them. Scientifically acceptable (in Lakatos' terminology 'theoretically progressive') modifications always have some additional testable implications and are thus not purely *ad hoc*. If some of the new predictions are confirmed, then the modification is 'empirically progressive' and one has reason to reject the unmodified theory and to employ the new theory, regardless of how unsuccessful, in general, either theory may be. Though progress may be hard to come by, Lakatos' views do not have the same destructive implications as Popper's. Lakatos appears to solve Mill's problem by arguing that what matters is empirical progress or retrogression rather than empirical success or failure. It is thus easy to see why Lakatos' views have become more widespread among economic methodologists than Popper's. Developing Kuhn's notion of a 'paradigm' (1970) and some hints from Popper, Lakatos also developed a view of the global theory structure of whole theoretical enterprises, which he called 'scientific research programmes'. Lakatos emphasized that there is a 'hard core' of basic theoretical propositions that are not to be questioned and that substantial heuristics guide members of a research programme in the articulation and modification of specific theories. These views were also attractive to economic methodologists, since theory development in economics is so sharply constrained and directed, and since economics appears at first glance to have a hard core. The fact that economists do not give up basic theoretical postulates that appear to be false might be explained and justified by regarding them as part of the hard core of the neoclassical research programme.

Yet Lakatos' views do not provide a satisfactory solution to Mill's problem. For it is questionable whether the development of neoclassical economic theory has demonstrated empirical progress. For example, the replacement of 'cardinal' utility theory by 'ordinal' utility theory in the 1930s, which is generally regarded as a major step forward, involved the replacement of one theory by another that was strictly weaker and which had no additional empirical content. Furthermore, despite his emphasis on heuristics as guiding theory modification, Lakatos still emphasizes testing. Science is for Lakatos a much more empirically driven enterprise than is contemporary economics Hands (1991). It is also doubtful whether research enterprises in economics have hard cores (Hoover 1991; Hausman 1992, ch. 6). For attempts to apply Lakatos' views to economics, see Latsis (1976) and Weintraub (1985). As is apparent in de Marchi and Blaug (1991), writers on economic methodology have in recent years become increasingly disenchanted with Lakatos' philosophy.

There is a second major problem with Popper's philosophy of science, which plagues Lakatos' views as well. Both defend the startling thesis that there is no such thing as empirical confirmation. Popper and Lakatos deny that the results of testing can give one reason to believe that statements are true, and both deny that results of tests can justify relying on statements in practical endeavours or in theoretical inquiry. They would accordingly regard as mistaken any claim that there is better evidence for one unfalsified proposition than for another. Someone who questions whether there is enough evidence for some proposition to justify relying on it in theoretical studies or for policy purposes would be making the methodological 'error' of supposing that there can be evidence in support of hypotheses. With the notable exception of Watkins (1984), few philosophers within the Popperian tradition have faced up to this radical consequence.

6 Contemporary directions in economic methodology

The failure of Friedman's, Popper's, and Lakatos' views to solve Mill's problem has had little impact on most economists, who are little concerned with methodology and who, when pressed, typically defend a position like Friedman's. But those specifically concerned with methodology have turned in many new directions, of which only three will be discussed here. Especially notable among the projects not discussed here are Lawrence Boland's neo-Popperian views (1989), Bruce Caldwell's 'methodological pluralism' (1982), Uskali Mäki's realist philosophy of economics (1990), Phillip Mirowski's exploration of the metaphorical structure of economics (1990), and E. Roy Weintraub's social constructivism (1991). There has also been a substantial effort to apply structuralist views of scientific theories to economics Stegmüller *et al.* (1982; Balzer and Hamminga (1989), and recently there have been some discussions of economics from feminist perspectives Ferber and Nelson (1993).

One radical reaction to the failure to solve Mill's problem is to deny that it can be solved. In Alexander Rosenberg's view (1992), economics can only make imprecise 'generic' predictions, and it cannot make progress, because it is built around folk psychology, which is a mediocre theory of human behaviour which (owing to the irreducibility of intentional notions) cannot be improved. Complex economic theories ought to be valued as applied mathematics, not as empirical theory. Since economics, despite its many well-trained practitioners, does not show the same consistent progress as the natural sciences, one cannot dismiss out of hand Rosenberg's suggestion that economics is an empirical dead end. But his view that it has made no progress and that it does not permit quantitative predictions is hard to accept. For example, it seems that contemporary economists can do a much better job of predicting the revenue consequences of a change in tax rates than could economists of even a century ago.

An equally radical but opposite reaction is Donald McCloskey's. He would solve Mill's problem by repudiating methodology. In McCloskey's view, the only relevant and significant criteria for assessing the practices and products of a discipline are those accepted by the practitioners. Apart from a few general standards such as honesty and a willingness to listen to criticisms, the only justifiable criteria for any conversation are those of the participants. The pretensions of philosophers to judge the discourse of scientists are arrogant and may be dismissed. Mill's problem dissolves when economists recognize that philosophical standards of empirical success may be safely ignored. Those who are interested in understanding the character of economics and in contributing to its improvement should eschew methodology and study instead the 'rhetoric' of economics - that is, the means of argument and persuasion that succeed among economists.

McCloskey's studies of the rhetoric of economics have been valuable and influential (1985, esp. ch. 5-7), but much of his work consists not of such studies but of philosophical critiques of the pretensions of methodology. These are more problematic, because the position sketched in the previous paragraph is hard to defend and potentially self-defeating. It is hard to defend, because epistemological standards for good science have already infected the conversation of economists. The standards of predictive success which give rise to Mill's problem are standards that economists already accept. Mill's problem can be dissolved only if economists can be persuaded to surrender the standards that gave rise to it. But the position sketched in the previous paragraph makes it difficult to argue for any changes in standards. Furthermore, as Alexander Rosenberg has argued, it seems that economists would doom themselves to irrelevance if they were to surrender standards of predictive success, for it is upon such standards that policy decisions are made. McCloskey does not, in fact, want to preclude all 'external' criticisms, which maintain that economists are sometimes persuaded when they should not be or are not persuaded when they should be. For he criticizes the conflations of statistical significance with economic importance, which are, as he

documents, nevertheless extremely common (1985, ch. 9). Sometimes McCloskey characterizes rhetoric descriptively as the study of what in fact persuades, but sometimes he characterizes it normatively as the study of what ought to persuade (1985, ch. 2). And if rhetoric is the study of what ought to persuade, then it is methodology, not an alternative to methodology. Mill's problem cannot be conjured away.

A third approach is to return to Mill's own solution. Many of the basic principles of economics are plausible and are borne out in everyday experience. Although such plausibility does not place these principles beyond question, it does provide some warrant for them and some warrant for what may be deduced from them. Given the weakness of tests involving market data, in which there is an uncontrolled multiplicity of causal factors, it may be reasonable to hang on to orthodox theory in the face of disconfirmation. This thought can be rigorously supported in terms of Bayesian confirmation theory Hausman (1992, ch. 12).

Yet this restoration of something like Mill's solution is in many ways as close to Rosenberg's and McCloskey's views as it is to Mill's. For the recognition that market tests will generally be too weak to shake the initial plausibility of the basic principles is simultaneously a recognition that there is little to be learned from market data. Although not quite as hostile to the empirical claims of economics as is Rosenberg's position, this view holds out few hopes for major improvements in economics. (By seeking higher quality data from observational studies and particularly experiments (see Roth 1988), economists may however be able to find a way out of this impasse.) On the other hand, in its insistence that one study the specific problems and constraints that economists face, this view joins McCloskey's in calling for less philosophically blinded studies of the rhetoric of economics (although it does not, of course, accept McCloskey's condemnation of epistemology).

7 Conclusions

Contemporary economic methodology is in turmoil. It has become an active area of research engaging major efforts by dozens of economists and a small group of philosophers. Economics presents a tantalizing list of puzzles, with Mill's problem at the core. And these problems have a special philosophical interest because of the connections between economics and ethics and between economics and the theory of rationality. There is much that is unknown and puzzling about how much people can learn about the character of their interactions and about what methods are most likely to help them to learn more. Economics is one exciting venue in which these general problems can be raised, but it has not, as yet, provided any easy solutions.

Education, history of philosophy of

The philosophy of education may be considered a branch of practical philosophy, aimed ultimately at the guidance of an important aspect of human affairs. Its questions thus arise more or less directly from the features of educational practice and the role of education in the promotion of individual and social wellbeing, however much its answers may be conditioned by the larger philosophical and historical settings in which they are posed. Philosophers have concerned themselves with what the aims of education should be, and through what forms of instruction, inquiry and practice those aims might be attained. This demands attention to the contents of instruction and who shall have authority over it. It demands attention to the nature of instruction itself, its epistemic dimensions and what is entailed by its reliance on language; the nature of learning and human development, both moral and intellectual; and how all of these are interrelated. The philosophy of education thus stands at the intersection of moral and political philosophy, epistemology, and the philosophy of mind and language, as they bear on the foundations of educational practice.

The philosophy of education began in classical antiquity with the challenges posed by Socrates to the educational claims of the sophists. Plato and Aristotle developed systematic theories of education guided by an ethic of justice and self-restraint, and by the goal of promoting social harmony and the happiness or wellbeing of all citizens. The Stoic descendants of Socrates were expelled from Rome and the oratorical model of higher education given official sanction, but Augustine re-established the philosophical model through a synthesis of Platonism and Christianity, and in his mature educational thought brought elements of the oratorical and Platonic models together in his account of the Christian teacher's training.

The religious wars of the Reformation inspired several philosophical stances toward the relationships of Church, state, school and conscience. Hobbes argued for a consolidation of ecclesiastical and civil authority, with full sovereign authority over education; Locke for liberty, religious toleration, and private education aiming at self-governance in accordance with reason; and Rousseau not just for the free development and exercise of the full array of human faculties, but for the establishment of a civic religion limited to the core of shared Christian beliefs which Enlightenment figures from Descartes onward had thought evident to natural reason.

The Enlightenment's embrace of science and reason yielded efforts towards the development of a science of learning and pedagogy in the nineteenth century, but Rousseau's romantic reaction to it and defence of democracy were also powerful influences. In the twentieth century, Dewey produced a new synthesis of Enlightenment and Rousseauian themes, drawing on Hegel, the experimentalism of Mill, evolutionary theory and psychology, and aspects of the substance and intent of Rousseau's pedagogy.

1 Socrates and the sophists

Educational philosophy began in the Greek classical period with the examination of the educational claims of the sophists undertaken by Socrates. The sophists brought higher education to the democratized Athens of the fifth and fourth centuries BC, offering those who aspired to political leadership a training in political *aretē* (the goodness, excellence or virtue required for success in pursuing appropriate ends) or *phronēsis* (sound judgment or practical wisdom) (see Aretē; Sophists). This form of education suggested that most citizens lacked the virtue and judgment required for a life in public affairs, and one can detect a concession to the political dangerousness of this in the claims of Protagoras that cities and their citizens do indeed teach virtue to the young, but that his own teaching could refine and develop it by degrees. In Plato's *Protagoras*, Socrates exposes the tensions in this view by distinguishing between the habitual virtue of good or obedient citizens, and true virtue which involves intellectual insight and sound judgment (that is, *phronēsis*), noting that a skill which merely refines and enlarges the former cannot yield the latter.

More generally, the Socratic response to the sophists was above all cautionary. As we encounter Socrates in the *Protagoras* and other early dialogues of Plato, he dedicated himself to showing through his method of questioning (*elenchus*) that those who claimed to be teachers of *aretē* lacked the expert knowledge of it which its teaching would require. The possession of such knowledge would allow one to defend and explain the truths one believes through a reasoned account (*aitias logismos*), and Socrates denied that he was himself a teacher, apparently on the grounds that he was unable to give such an account of his own beliefs. He advocated the individual care of one's

own soul, and embraced an ethic of justice, wisdom and self-restraint, in opposition to the competitive ethic of the warrior heroes portrayed by Homer and embraced by Greek popular morality. How far he thought his own elenctic method would carry one in this care of the soul, or in the search for the best way to live, is unclear (see Socrates).

2 Plato and Aristotle

The adequacy of the Socratic *elenchus* was evidently one of Plato’s concerns in the *Meno*, for the work presents us with a Socratic interlocutor who is purged of misplaced confidence and ready to join Socrates in a search for the nature of virtue, but asking how the search is to go forward without the benefit of any knowledge of the object of the search. This prompts the introduction of Plato’s theory that all learning is recollection, and a demonstration of an *elenchus* arriving, without recourse to prior knowledge, at the discovery of a geometrical fact. The theory of recollection underwrites the hope that a search will yield truth, by suggesting that one can count on having enough true beliefs to drive out the false, as one’s beliefs become more coherent under questioning. Plato implies that one ascends from there to knowledge as one reasons through the relationships among all the truths in the relevant domain and can thereby understand and provide an explanatory account of any one of them.

In the *Republic*, Plato envisages the inculcation of self-restraint through a comprehensive system of compulsory education for each social class, and develops an elaborate defence of the Socratic thesis that justice is a virtue indispensable for a happy life. Plato was evidently concerned that the education of his time, which was dominated by the study of Homer, was inconsistent with the inculcation of these virtues, and regarded an education which would eliminate unnecessary desires for contested goods as the one way to eliminate wars of conquest and the political instability so prevalent in Greek life. He envisages a craft training for members of the labouring class, which will free them from the dominance of desires for unnecessary consumption and prepare them for a happy life of efficient money making. Members of the ‘guardian’ class are to be given a communal upbringing which will eliminate conflict arising from clan loyalties, and a primary education in music, athletics and stories which will enable them to be happy in their pursuit of honour by making them courageous and gentle towards each other and those they protect. The philosopher-kings must know what is good for the city, and Plato proposes an education which will not only elevate their minds through the study of abstract sciences to dialectic and apprehension of the transcendent ‘Form’ of goodness, but also provide many years of experience in the affairs of the city.

Plato’s *Laws* describes a city which resembles that of the *Republic* in aiming at the virtue and happiness of all citizens, but is quite unlike it in being a constitutional rule of law grounded in reason and informed consent. The insistence on consent, and an unwavering commitment to the idea that every institution, including legislation and its enforcement, is educative, leads to the proposal that all laws be prefaced with ‘preludes’ that are both moving and explanatory, and that these ‘preludes’ should serve as models for the literary substance of state-operated day schools. Two noteworthy aspects of the theory of learning and instruction at work in the *Laws* are the prominent role assigned to guided practice, and its rich use of the model of a good doctor who communes with and earns the trust and cooperation of a patient before prescribing a remedy. It shares with the *Republic* the view that rational self-control and the ability to perceive what is good can only develop under the influence of good upbringing and education.

Aristotle’s *De Partibus Animalium (On the Parts of Animals)* opens with a characterization of a complete education as one which enables a person to form reasonable judgments of the goodness or badness of reasoning in all branches of knowledge. This requires an understanding of the manner and canons of investigation in the various branches of knowledge, and it is fair to say that Aristotle dedicated himself not only to the discovery and elaboration of those canons of investigation, but also to making them known through his lectures and the wide-ranging scientific investigations of his ‘school’, the Lyceum.

Of the works of Aristotle that have survived, it is the *Politics* and *Nicomachean Ethics*, the works of ‘political science’ intended as guides to political practice, that are most revealing of his educational philosophy. They suggest that he thought a higher education for political *phronēsis* should provide leaders and their advisors with systematic knowledge of how to pursue the proper aim of the state (namely, the best kind of life for all its citizens), and a knowledge of the causes of dissolution of states which would provide corrupt leaders with the motivation to pursue reforms. Plato had argued that unjust regimes tend to be short-lived, and Aristotle offered his own comparative study of 158 constitutional histories as confirmation.

Aristotle shared Plato's view that justice and human wellbeing require systematic educational efforts to make citizens virtuous and to create social unity, but his accounts of education for good character and unity are interestingly different. His view of *aretē*is that what is essential to it, beyond being disposed to desire the right ends and take pleasure in their attainment, is judging and acting from a well-rounded grasp of the morally important particulars of the situations one faces. The beginnings of *aretē* must be established through exposure to good models and habitual obedience to good law, but its refinement requires practice guided by coaching and correction. This progress in perception, responsiveness and judgment reaches its highest development through conversation with trusted and exemplary companions who can best enable one to know oneself.

Aristotle was critical of the communism of the *Republic*, and followed the Plato of the *Laws* in proposing the establishment of state-sponsored day schools. He seems to have regarded common schooling, and its proposed education for virtue, as the natural culmination of reforms by which a city can be unified through the cultivation of goodwill, common non-competitive aspirations, and friendships which bridge the divides between different social classes.

3 Hellenistic and Roman education

The conquests of Alexander the Great brought an end to any hope that the fulfilment of human nature could be achieved through the educational and political efforts of an autonomous *polis* or city-state. Philosophy of education thereby lost its connection to public life in the Hellenistic Age, and what remained of it in Stoicism was the doctrine that an understanding of divine reason allows one to be happy, good and free of the tyranny of unnecessary desires, by enabling one to accept the inevitability of lacking what one does not have and cannot possess. The Stoics took divine reason to be manifested in the order of nature, and Chrysippus and others apparently held that an adequate understanding of nature is best attained through a study of logic and physics (see Stoicism §3).

Rome had no need for a philosophy withdrawn from public life, and when the Emperor Vespasian granted the first public subsidy for higher learning in the first century, it went to the school of rhetoric operated by Quintilian. His work, the *Institutio Oratoria (The Training of the Orator)*, is both a textbook of rhetoric and a treatise on the principles of education, and it exercised a powerful influence on Western educational ideals well into the nineteenth century. Quintilian took the highest aim of education to be the formation of a perfect orator, a person made both eloquent and good through exercises in composition and declamation, and a broad study of the liberal arts and rhetorical theory.

4 Augustine and Aquinas

Augustine is regarded, with justice, as not only the primary architect of the synthesis of Christianity and Platonism on which Christian theology was built, but also the foremost philosopher of education of late antiquity and of Catholicism generally. He was trained as an orator and held teaching posts in rhetoric for twelve years, but upon his conversion to Christianity in 386 he renounced the shallow worldliness of the oratorical ideal, setting himself and the philosophy of education upon a new course. Fundamental to Augustine's view of education is the idea that its proper goals are first of all conversion and repentance, or the acceptance on faith of Christian beliefs and a commitment and effort of will to live without sin; and secondly, for the few who can achieve it, a wisdom consisting of direct knowledge of the soul and God through reason, or the insight of an intellect directed inwardly.

Augustine's view of the course of higher studies preparatory for the attainment of this wisdom, and for its use by the Christian teacher, underwent a marked development between the educational works written in the first years after his conversion and those finished after he was consecrated bishop of Hippo in 395. The mainsprings of this development were a dramatic growth in his respect for biblical Scriptures as the word of God, which led him to revise his view of the role and value of liberal studies, and an appreciation for the value of rhetoric which grew with his responsibilities in the Church.

In his *De ordine (On Order)*, Augustine affirms the existence of an all-embracing Divine order, knowable through liberal studies which allow one to grasp the pervasive reasonableness in things emanating from God's intellect or Logos. It is dialectic or philosophical reasoning which teaches one how to learn and how to teach, he says, and this is compatible both with his view that the soul must prepare itself to see God through the exercise of its own reason,

and his view in *De magistro (The Teacher)* that knowledge of a thing is achieved in *seeing* it, not in hearing someone name or describe it. He argues there through a theory of signs and language that teaching through words cannot enable us to know things by displaying them, but can only remind or prompt us to consult our own divinely illuminated reason, or else induce us to believe things on trust without understanding or knowledge.

Augustine's *De catechizandis rudibus (Catechizing the Uninstructed)* develops a curriculum for the uneducated which is intended to induce moral behaviour and faith in God sufficient for salvation. His *De doctrina christiana (Christian Instruction)* explicates the training and methods through which Christian teachers may properly interpret biblical Scripture and teach the truths discovered in them. He prescribes a course of studies encompassing languages, history, geography, natural science, technology, logic and mathematics, all as an aid to understanding scripture, and offers canons of interpretation by which the Christian teacher may distinguish the literal from the allegorical, and find the hidden meaning in the latter. Rhetoric returns in the service of faith and love of God and neighbour, in the training of the Christian teacher and in detailed guidance on how the truths discovered in scripture are best presented.

The embrace of Aristotle by Thomas Aquinas produced a second major synthesis of classical and Christian thought, and a philosophy of teaching which owes much to both Aristotle and Augustine. Aquinas argues that acquiring knowledge by discovery and by instruction are alike in that a teacher can only lead a student to knowledge by making manifest to them the discursive reasoning through which discoveries are made. 'Outward' teaching may thus produce knowledge by aiding the student in reasoning through the application of self-evident general principles to particular matters, though it is God who teaches 'inwardly' by endowing the mind with the 'light of reason' and a knowledge of these first principles.

5 The Renaissance and Reformation

The Renaissance and Reformation are noteworthy in educational history on many grounds, including the incorporation of the educational ideals and programme of Quintilian into the Christian humanism of Desiderius Erasmus and others; Martin Luther's translations and promotion of universal, publicly-funded elementary education, so that the common people might read and thereby consult for themselves the Scriptures (see Luther, M.); and the founding of the Jesuit order and its system of colleges by Ignatius Loyola. What inspired the most weighty philosophical response, however, was the turbulent course of the Reformation itself, and the urgent questions it raised about the relationships between church, state, school and individual conscience.

Thomas Hobbes has been neglected by histories of philosophy of education, but a central concern of his *Leviathan* was to establish the desirability of uniting civil and ecclesiastical authority in a sovereign empowered to use public education to inculcate correct religious and moral beliefs. In both *Leviathan* and *Behemoth*, his history of the English Civil War, he attributed social disorder, including conflict and civil war arising from the exercise of individual judgment in religious matters, to faulty instruction from the pulpit and in the universities. This instruction not only incited conflict over theological questions without answers, he argued, but spread doctrines contrary to the natural law of civil and moral duty. Because these doctrines shaped a conception of religious interests linked to the expectation of an afterlife, Hobbes regarded attempts to suppress rebellion by force as futile, and argued that sovereign authority over education and the interpretation of scripture was desirable and necessary to ensure peace.

6 Descartes and Locke

René Descartes' remarks on education are continuous with the classical tradition in identifying universal wisdom as the greatest good and proper aim of instruction, but he turned a deeply Augustinian account of reason against the curricula of Augustine, Aquinas and the scholastic university, and championed the free and methodical exercise of individual reason or self-instruction as the surest path to wisdom and the progress of science and human emancipation. He regarded the unrestrained use of reason in the pursuit of understanding as a natural and desirable expression of human nature, and held that the individual intellect can easily discover within itself a knowledge of God, the soul and good actions. Thus, he regarded the inward gaze of reason itself as the best guide for the conduct of life, and the means through which theological disagreements and the conflict arising from them may be resolved. However, he held that the purging of prejudice through doubt or the suspension of belief is a necessary prerequisite to the effective employment of reason.

With regard to the curricular proposals of Augustine, Descartes maintained that the revealed truths of Scripture are beyond the intelligence of even the best trained interpreter, and that in general it takes more skill to find what is true in books than to discover the truth for oneself. In answer to Aquinas and the scholastic tradition, he argued that instruction through syllogistic deductions undermines both the freedom and power of reason, because syllogistic deduction does not ensure any intellectual grasp of the propositions involved and does not enable one to discover new knowledge. Exercise with inquiries conducted on his own more natural method of reasoning is the recommended alternative (see Descartes, R. §2).

Descartes laid the foundations for the educational philosophy of the Enlightenment, but it remained to John Locke to provide an influential articulation of it. Locke deepened Descartes' attack on second-hand knowledge by combining the latter's view that knowledge can only be obtained through the perception of 'clear and distinct' ideas, with his own systematic development of the claim that one can only acquire ideas through one's own experience. With this epistemic individualism as his starting point, he took the fundamental and humanizing goal of education to be the development of rational abilities and the habits of doubt, reflection and foresight required to form children into adults who will judge and act in accordance with the dictates of reason. This is consistent with his having put virtue, wisdom, and 'breeding' (that is, respect for self and others) before learning or the acquisition of knowledge, since he regarded virtue as a disposition to follow one's desires only when doing so accords with the dictates of reason or natural moral law. Autonomy of judgment and action are thereby reconciled with virtue and sociability through the concept of self-mastery, and education is to be first and foremost a process of habituation to self-mastery.

Locke held that parents have a natural duty to educate their children to be self-governing and able to provide for themselves, but he proposed public action to ensure that even children of paupers would receive instruction in Christian morality and a trade: those who will never have the leisure for knowledge or science would have little use for more than this, he suggested. For the sons of landed gentry he counselled a general education through private tutelage, aimed to produce gentlemen ready to contribute to the wellbeing of the community. This education should encourage a breadth of experience and inquiry reaching down to the foundations of beliefs, and promote reflection on desires by refusing to gratify those that are excessive. It should exercise firm but gentle authority over the child, appeal early and often to the child's reason, and make education enjoyable since autonomous learning cannot be coerced (see Locke, J. §9).

7 Rousseau and Kant

The concern that animates the educational and political thought of Jean-Jacques Rousseau is the preservation of the freedom and goodness which he took to define human nature, in opposition to the Enlightenment conception of humanity as essentially rational, progressing towards happiness and the perfection of its nature through the cultivation of reason. Rousseau argued in his first and second *Discourses* that what the arts and sciences encourage are sentiments of self-love and ambition which are destructive of our goodness and freedom, leading us to an insatiable pursuit of private gain at the expense of the common good. To this image of fallen humans, rooted in the orthodox identification of pride as the 'root of all evil', he coupled a further challenge to the hope that progress might be achieved through the ascendancy of reason, observing that in such a state of society the voice of individual reason will counsel free-riding, the unjust enjoyment of the rights of citizenship without the discharge of corresponding duties.

Rousseau held in his *Émile*, the most influential educational tract of the modern era, that in order to educate a boy both for himself and for society, one must preserve his natural freedom and goodness by conforming the education of 'humans' and 'things' to nature's timetable for the development of his faculties and motives. Children are moved first by the expectation of pleasure and pain, later by a grasp of what is useful, and finally by reason; and they should learn at each stage through experience and feeling, not through books or the imposition of discipline or teaching. The tutor need do little but shield the child from the corrupting influence of society and organize his activities (and thereby his experiences and feelings) in order to nurture the growth of moral sentiments and conscience, of a self-sufficiency grounded in prudence and mastery of a craft, and of his faculties and knowledge of the world, God and moral law. Freedom from material reliance on others and from the domination of excessive desires is thus assured.

By contrast with Locke, Rousseau held that freedom from domination by others requires that the child's behaviour

be corrected solely by the experience of the natural consequences of actions, and that adults make law for themselves through a form of democracy in which the citizens retain and exercise direct legislative sovereignty. Good citizenship requires, however, that they aim at the common good when it conflicts with their private ends, and Rousseau envisages in *On The Social Contract* a 'Great Legislator' who proposes good laws and persuades the public to enact and obey them through neither force (which would negate freedom) nor rational argument (which wouldn't solve the free-rider problem). The legislator must teach by example and through a 'natural' civil religion, established not as dogma but as sentiments of sociability (see Rousseau, J.-J. §3).

Immanuel Kant's philosophy of education is like Rousseau's in being grounded in a philosophy of history, but it reaffirms not only the essential rationality of human nature, but also original sin and the naturalness of discord and competitive self-love. His conception of the end for which we were created is that our rational nature should find full expression, that we should achieve moral perfection through effort and the grace it occasions, and that we should thereby become both happy and worthy of that happiness. This future kingdom of heaven on earth is what children should be educated for, but the stages of their education must first recapitulate the stages of human history already traversed. The first of these is nurture; the second discipline, to counterbalance natural unruliness; the third is culture (information and instruction), to develop ability and prudence; the last (for the world order yet to come) is moral training, to encourage respect for moral law and an acceptance of its priority over self-love as the principle of one's will.

8 The nineteenth century

The nineteenth century was a period of unprecedented innovation in the theory of learning and the theory and practice of pedagogy, particularly in Germany. From a philosophical standpoint this activity can be described most simply as a playing-out of Enlightenment ideas and of the romantic and aesthetic reactions to them initiated by Rousseau and Friedrich von Schiller. Johann Heinrich Pestalozzi (1746-1827) and Friedrich Wilhelm Froebel (1782-1852) were the most prominent of those strongly influenced by Rousseau, the former being known for a pedagogy grounded in the analysis of tasks into simple components, his advocacy of universal educational rights and efforts to educate the poor 'organically' in a family-like setting; the latter for founding the kindergarten as a place of growth in unity with God and nature. Johann Friedrich Herbart is noteworthy for his attempts to develop the experimental science of pedagogy envisaged by Kant, and for a theory of ideas and learning which held that it is 'apperceptive masses' formed by past experience that structure new experiences, allowing the assimilation of ideas that are compatible but driving from consciousness those that are not.

Though not a philosopher of education himself, Karl Marx has figured importantly in the subsequent history of the field through, among other things, his theory of ideology, an exceedingly influential if unsystematic account of the way in which socioeconomic roles and the ideas that structure them are learned through contact with a society and its institutions. Contraposed to the radical egalitarianism of Marx was the radical elitism of Friedrich Nietzsche, the other great immoralist of the nineteenth century, who condemned the democratization of the universities on the grounds that the reversal of cultural decadence and advancement of human wellbeing through the free play of creativity requires that higher education remain the exclusive province of 'higher types'.

9 John Dewey

John Dewey is regarded with justice as the pre-eminent philosopher of education of the twentieth century. Like Marx and Nietzsche, he understood the function of philosophy to be social and cultural reconstruction, and like Marx he aspired to reconstruct philosophy itself by bringing science into it. But he rejected the teleological conceptions of history embraced by Marx, Hegel and Kant in favour of a kind of evolutionary naturalism. He took this naturalism to preclude the existence of absolute norms of conduct, and to warrant recognition of a plurality of goods and moral criteria. If there is any 'end' entailed by human nature it is growth itself, he argued and, following Rousseau, he held that a good society is one in which growth is maximized, harmonized with that of others, and reconciled with the collective work of citizenship. He argued, much as Rousseau did, that democracy is the one form of political life in which the convergence of these goals is possible, and he adopted and developed John Stuart Mill's idea that social progress is possible through the freedom of individuals to engage in social experimentation, or the application of the methods of science to the problems of social existence (see Mill, J.S.). Dewey insists that this experimentation or application of 'social intelligence' must be cooperative, governed by the norms of respectful communication, and guided by the plurality of goods and criteria valued by those whose

interests are at stake. He thought that in this way the Enlightenment promise of social progress through the application of scientific method might be achieved simultaneously with enacting democracy as 'a way of life' in which human growth and quality of experience can be optimized.

Experience became for Dewey both the goal and means of education: the richness of future experience its goal, and present experiences which engage the student's activity and improve the prospect of desirable experiences in the future its means. His methodological Hegelianism, or strategy of undercutting the dualisms dividing one school of opinion against another, is as evident in his philosophy of education as elsewhere. He resisted the duality of thought and action, book learning and vocationalism, pedagogy driven by a preconceived curriculum and pedagogy driven by the antecedent interests of the child. Above all, he held that the social world of the school and of a properly democratic society must coincide, and that the exercise of intelligence and engagement in adaptive conduct are inseparable. Classrooms must therefore be devoted to the collaborative activity of inquiry, he concluded (see Dewey, J.).

Education, philosophy of

The philosophy of education is primarily concerned with the nature, aims and means of education, and also with the character and structure of educational theory, and its own place in that structure. Educational theory is best regarded as a kind of practical theory which would ideally furnish useful guidance for every aspect and office of educational practice. Such guidance would rest in a well-grounded and elaborated account of educational aims and the moral and political dimensions of education, and also in adequate conceptions and knowledge of teaching, learning, evaluation, the structure and dynamics of educational and social systems, the roles of relevant stake-holders and the like.

Philosophers of education often approach educational issues from the vantage points of other philosophical sub-disciplines, and contribute in a variety of ways to the larger unfinished project of educational theory. These contributions may be divided into work on the nature and aims of education, on the normative dimensions of the methods and circumstances of education, and on the conceptual and methodological underpinnings of its methods and circumstances - either directly or through work on the foundations of other forms of research relied upon by education theory.

Philosophical analysis and argument have suggested certain aims as essential to education, and various movements and branches of philosophy, from Marxism and existentialism to epistemology and ethics, have suggested aims, in every case controversially. Thus, one encounters normative theories of thought, conduct and the aims of education inspired by a broad consideration of epistemology, logic, aesthetics and ethics, as well as Marxism, feminism and a host of other '-isms'. In this mode of educational philosophizing, the objects of various branches of philosophical study are proposed as the ends of education, and the significance of pursuing those ends is elaborated with reference to those branches of study.

A second form of educational philosophy derives from substantive arguments and theories of ethics, social and political philosophy and philosophy of law, and concerns itself with the aims of education and the acceptability of various means to achieve them. It revolves around arguments concerning the moral, social and political appropriateness of educational aims, initiatives and policies, and moral evaluation of the methods, circumstances and effects of education. Recent debate has been dominated by concerns about children's rights and freedom, educational equality and justice, moral and political education, and issues of authority, control and professional ethics.

The philosophy of education has also sought to guide educational practice through examining its assumptions about the structure of specific knowledge domains and the minds of learners; about learning, development, motivation, and the communication and acquisition of knowledge and understanding. Philosophy of science and mathematics have informed the design of curriculum, pedagogy and evaluation in the teaching of science and mathematics. Philosophy of mind, language and psychology bear on the foundations of our understanding of how learning occurs, and thus how teaching may best promote it.

1 Philosophical analysis and theory

Philosophy of education emerged in the second half of the twentieth century as a distinct branch of philosophy, devoted to the systematic study of education through the methods of conceptual analysis and the methods and findings of other, more established philosophical sub-disciplines and movements. This was evident in the creation of journals and societies of philosophy of education, but more importantly in the work of Richard Peters, Israel Scheffler and others who recast philosophy of education in an analytical mould and brought educational philosophizing in the schools and departments of education of the English-speaking world into closer contact with mainstream philosophy.

This process of recasting the methods of philosophy of education had begun in the 1940s with the work of C.D. Hardie, but at mid-century what mostly passed for educational philosophy was a lengthy menu of 'educational philosophies' consisting of little more than restatements of a common stock of wisdom about schooling in the vocabularies of various 'schools' of thought. These pragmatist, idealist, realist and other philosophies of education were grounded in the conviction that a philosophy of education can be derived from the tenets of any

‘philosophical school’, a mistake whose continuing influence is evident in more recent attempts to develop existentialist, phenomenological, hermeneutical, postmodernist and other philosophies of education.

As it developed from the late 1950s to the 1970s, analytical philosophy of education was centrally concerned with the analysis of educational concepts such as ‘teaching’, ‘learning’, and ‘understanding’. A good example of this kind of work is Scheffler’s (1960) analysis of teaching as involving an intent to bring about learning, the use of instructional strategies reasonably calculated to engender it, and a manner respectful of the learner’s rationality. An extensive literature developed around this ‘standard thesis’, generating alternative analyses and accounts of quality in teaching, the boundaries between indoctrination and teaching, and the nature of learning. Some of this was illuminating and may have helped to clear away confusions and false assumptions about teaching in the literature of educational studies and reform, but conceptual analysis was a tool of limited efficacy in a domain lacking the sorts of metaphysical problems that Wittgenstein, Austin and Ryle had been at pains to resolve. The analysis of educational concepts went forward with neither the larger philosophical purposes of the formal and ordinary language movements themselves, nor the normative resources which the great educational theories of philosophy’s past had brought to bear on practice (see Analytical philosophy; Ordinary language philosophy, school of).

Work on this core of distinctly educational concepts had declined so substantially by the 1980s that one might reasonably judge that philosophy of education had lost its identity as a distinct sub-discipline and been reabsorbed into the parent discipline and its sturdier progeny. In any case it has been relatively inconspicuous in an era when other domains of practical philosophy have enjoyed spectacular growth and development, even as its scattered remains have been reinvigorated by the richer methods and bodies of work that have developed in ethics, political philosophy, informal logic and philosophy of the sciences, and by an outpouring of scholarship on the history of philosophy that is both philosophical and seriously historical. Philosophers of education had never ceased to engage the history of their field, but they are now in a position to do so more profitably.

The rich and largely untapped opportunities at hand are best pursued with a reasonable conception in view of the ways in which the philosophy of education can appropriately contribute to the larger enterprise of educational theory. This requires a model of the structure of a theory of education and of the place of philosophy of education within it.

Frankena (1965) and others have defended the view that philosophy of education must be regarded as principally an offshoot of ethics, and Hirst (1983) has formulated a plausible view of educational theory as a systematic body of practical principles generated, tested and justified by practice as much as through research in the disciplines. But a full account of the ways in which philosophy can contribute to the development of educational theory has yet to be synthesized. Broadly speaking, one can say that a fully elaborated theory of education would span education’s aims and means, its patients, practitioners and beneficiaries, its manner, mode and circumstances of provision, providing practical guidance which both explains and justifies what is to be done. The subdivisions of philosophy contribute to this enterprise through suggesting and illuminating the character of possible goals of education (see §§2-4), justifying educational aims and providing normative guidance for various aspects of the provision of education (§§5-7), and through guidance regarding assumptions of fact about learning, development and the character of specific subject domains (§§8-9).

2 Epistemology and the curriculum

Philosophical theories of the curriculum have generally been guided either by ethical or political-theoretic arguments about the proper aims and constraints of education (see §§5-6), or by an embrace of the concerns of one or another of the philosophical sub-disciplines or movements. Existentialists have proposed authenticity and freedom as the aims which should guide teaching and the curriculum, Marxists and critical theorists propose social reconstruction or the abandonment of hierarchically imposed curricula, feminists a more girl-centred curriculum (see Existentialism; Feminism; Marx, K.). Epistemology commends knowledge as a worthy object of instruction, and provides some basic guidance in how to make it one.

Peters (1966) held in his early writings that education consists in initiation into the forms of knowledge evolved by society, both to develop the mind and to transmit a valuable heritage. Dewey had rejected knowledge-transmission models of education in favour of an emphasis on experimentation, problem-solving and critical thinking rooted in

the child’s prior interests (see Dewey, J.); Peters argued in response that the disciplines themselves supply the various forms of critical thinking and problems to be addressed, and that it is the teacher’s job to lead children beyond their present interests to a love of knowledge. Hirst (1973) developed a similar view of *liberal* education, arguing that the development of a rational mind is inseparable from initiation into the forms of knowledge, and that this initiation should involve an ‘immersion’ in the concepts and methods of the various forms sufficient to yield an understanding of how each works and to allow the learner to experience the world through their distinctive structures.

Epistemology clearly lacks the wherewithal to warrant such a narrow view of the curriculum, as Peters later recognized, but it may still provide guidance for education to the extent that knowledge or the development of an ability to acquire it is an acknowledged aim. Scheffler (1965) has perhaps made the most of what analytical epistemology has to offer, by developing the distinction between knowing-that and knowing-how, and examining the implications for teaching of the *belief* and *evidence* conditions for knowing-that. The former demands that classrooms engage students’ beliefs, rather than merely train them to give the right answers; the latter demands that they encourage internalization of the methods and forms of evidence by which knowledge is generated if students are to be epistemically autonomous.

Most of the recent literature has taken its cue not so much from philosophical epistemology as from a variety of movements built on unwitting adherence to remnants of logical positivism, confusion over the significance of debates about foundationalism, and epistemological scepticism rooted in theories of ideology and the incommensurability of paradigms (see §8). The dominant concern is that authority in school and society has rested illicitly on claims of epistemic authority.

3 Logic and critical thinking

Logic would seem to commend rationality as an educational goal or ideal, much as epistemology does, and to suggest that there are skills of reason or rational inference that can be isolated and taught independently of other aspects of the curriculum. Since the 1960s, however, there has developed a large body of work on critical thinking predicated on the inadequacy of formal deductive logic as an account of quality in inference, argumentation and reasoning. Formal logic has thus been largely set aside as a model for the teaching of critical thinking, though something of its spirit has been preserved in the idea of subject-neutral principles of reason assessment advocated even by those who regard critical thinking as no less epistemic than logical. This critical thinking movement has produced not only one of the more important streams of theoretical analysis undertaken in recent philosophy of education, but also innovations in curriculum and evaluation procedures at all levels of instruction.

Debate about the nature, teaching and evaluation of critical thinking was strongly influenced through the 1960s and 1970s by the work of Ennis (1962), who first conceived of critical thinking as correctly assessing statements, later as thinking that is reasonable, reflective and concerned with assessing not only beliefs, but also actions. His focus on discrete skills of reasoning has drawn a variety of criticisms.

McPeck (1990) has argued, against not only Ennis but the critical thinking movement generally, that there is no significant body of general critical thinking skills which can be taught. Citing Hirst, he argues that the subject-specific forms of inquiry we engage in have too little in common for us to extract a common logic which can be profitably taught as a subject in its own right.

Other philosophers have rebutted McPeck’s grounds for denying the existence of a robust set of subject-neutral critical thinking skills, while also arguing that there is more to being a critical thinker than possessing such skills. Paul (1982) has insisted that the mastery of atomic thinking skills only makes one a ‘weak sense’ critical thinker with the ability to criticize the views of others and reinforce one’s own. Exchanges of arguments involve clashes between opposing perspectives or world views, so to be a ‘strong sense’ critical thinker involves being able to take a sympathetic view of perspectives and world views one does not hold, he argues. Resisting the potential relativism in Paul’s view (see Relativism), Siegel (1988) has argued that it is ‘atomistic’ criteria of appraisal that we must rely on in judging worldviews. He holds that a critical thinker is one who is appropriately moved by reasons, one who possesses not only the abilities of rational assessment but a willingness, desire and disposition to follow reason. Lipman (1991) has argued that philosophy itself affords the best training in reasonableness and judiciousness guided by the ideal of rationality, and that it requires that we convert classrooms at all grade levels

into 'communities of inquiry' through conversation governed by norms of reasonableness and mutual respect.

These developments lay useful groundwork for an integration of work in philosophy of education with broader philosophical investigations of the nature of rationality and good judgment.

4 Aesthetics, perception and creativity

The precarious position of the arts and the aesthetic in contemporary education has lent urgency to questions about the aims and value of education in the arts. Philosophers of education have sought to answer these questions through engagement with philosophical aesthetics and the philosophy of art and literature. Their primary concern has been to elaborate a compelling vision of the value of a proper education in the arts; their assertions of value have rested sometimes in direct appeals to the quality of human experience, but more often in accounts of the contributions of the aesthetic to the cognitive, practical and productive aspects of human existence.

In work first published in the 1970s, Scheffler held that aesthetic experience is not simply emotional but also cognitive, and that in interpreting both art and the situations which confront us in life our feelings guide our perceptions (see (Scheffler 1991). Greene 1995) and Nussbaum (1990) have taken related lines of thought farther in arguing that education in the arts develops a perceptiveness which equips one well for life. The former has argued that the visual and performance arts embody distinct representational symbol systems whose mastery 'releases' the learner's perception and imagination, thereby liberating both judgment and action. The latter has brought an Aristotelian account of the development of virtue and practical judgment in defence of literary art, and the novel especially, for its value in cultivating the capacity to discern and respond to what is morally salient in concrete situations.

Philosophical interest in the productive and performance aspects of arts instruction has focused on the nature of creativity and how best to promote it. In opposition to the widespread belief that creative and rational thought are mutually exclusive, the tendency of recent philosophical work, such as Bailin (1988), has been to view significant achievement as the measure of creativity, and productive imagination as resting on knowledge and skill.

5 Ethics

Ethics holds a central place in philosophy of education through its role in justifying not only the aims and priorities of education, but education itself. Peters ((1966) shaped the course of debate with an argument for eschewing talk of aims and a non-instrumental justification of education, but by the 1970s the landscape was crowded with 'de-schoolers' and child liberationists who denied that imposing education on children is justified. The liberationists argued that children must be assigned the same liberty rights as adults, and held that the consequences of doing so would be benign. Purdy 1992) has refuted this most effectively, with a review of the evidence against the liberationists' optimistic assumptions about children's rationality and development in the absence of constraint, and with a defence of the legitimacy of moral education in government-run schools. She, Callan (1988) and others have nevertheless defended the importance of autonomy as a central goal of education, arguing in various ways that the development of autonomy is promoted by upbringing and teaching which nurture self-control, critical thinking, self-examination and related traits. Others have appealed to children's rights and wellbeing, the duties of adults and other forms of moral premises in defending educational aims ranging from various conceptions of the individual student's good to promotion of environmental responsibility.

R.M. Hare stimulated interest in moral education with his view, first adumbrated in *The Language of Morals* (1952), that what is important is that children should learn the *form* of morality so that they may find and embrace a set of moral principles of their own. Other prominent moral theorists followed his lead, generating a debate largely defined by the tensions between Kantian and Aristotelian views (see Kantian ethics). Kurt Baier (1973) and others took positions sympathetic to Lawrence Kohlberg's conception of moral development as a sequence of stages toward mature moral reasoning. Resisting both 'moral indoctrination' and treating the child's intuited 'values' as authoritative, they advocated instruction in moral reasoning that would enable a child to become morally autonomous or able to identify and apply rationally acceptable moral principles. Taking a more Aristotelian view, Pincoffs ((1986) defended moral habituation from the charge of indoctrination with the argument that it is only through such habituation that one can perceive and appreciate the moral qualities of things (see Aristotle §§21-3). He and Nussbaum have developed virtue-centred accounts of moral education which regard

the development of perception, affect and judgment as interrelated. Recent work has sought to join such approaches with accounts of care, trust and the psychosocial foundations of moral learning.

Educational ethics has become increasingly visible as a branch of professional and practical ethics not unlike medical or business ethics. This is particularly true of the ethics of higher education, which has flourished in eras of crisis in the universities such as the 1960s and 1990s. The topics that dominate current debate include curricular multiculturalism; university neutrality in the face of injustice or political controversy; university-business partnerships and other arrangements that may compromise academic integrity; the proper management of student life in the face of sexual harassment and violence, alcohol and drug abuse, and racism. Multiculturalism has also become an important focus of debate in the ethics of primary and secondary education, joining such topics as the ethics of student evaluation, discipline and classroom management, and the ethics of educational research (see Multiculturalism).

6 Political philosophy

Political philosophy has been a perennial source of reflection on the significance of education for civic life, and on the proper role of the state in overseeing and sponsoring education. The classical tradition took education to be an important instrument of statesmanship and civic well-being, while liberals such as John Stuart Mill regarded state sponsorship of education as a threat to liberty. Modern liberal democracies have neither fully accepted nor fully rejected either of these views in practice, nor have they fully accepted or rejected the liberal egalitarian idea that equal educational opportunity is essential to social justice. The tensions and tradeoffs involved in these compromised commitments generate ongoing debate, and provide an important context for assessing the import of the ethical endorsements of education for autonomy noted in §5.

A ‘liberal education’ is defined by ‘comprehensive liberals’, such as Ackerman 1980), as one that would provide children with the resources to develop their own self-conceptions and choose their own courses in life. This requires that it be nondirective with respect to substantive conceptions of the good, and promote autonomy grounded in rational scrutiny of the alternatives. ‘Political liberals’, such as Macedo (1995), argue in response that this requirement is not easily reconciled with liberalism’s own acceptance of diversity. Can one coherently endorse individual autonomy while denying parents the right to bring their children up in their own traditions and religion? Another line of argument which rejects comprehensive liberalism concerns itself with a perceived decline in civic commitment and a sense of sharing in a common good and belonging to a common social order (see Community and communitarianism; Liberalism).

Gutmann’s liberal democratic view of education (1987) is built on an uneasy alliance between this communitarian view and comprehensive liberalism. She holds that democracy requires that communities be able to shape their futures through democratic control of education, subject to the limits set by principles which demand, among other things, that all children be enabled through education to participate ‘effectively’ in democratic deliberations. In the face of widely divergent views of the prospects for creating an ‘educated public’ able to rationally engage in such deliberations, MacIntyre (1987) has derived an account of the conditions that are required, from a historical instance in which they were arguably present.

Marxist critiques of schooling and liberal meritocracy begin by noting the persistence of inequality, and historical connections between the rise of government-run school systems and the factory system. They conclude that the perpetuation of inequality has been essential to the role of schools in capitalist societies, their function being to sort students for different economic positions, in a way that masks the intergenerational transmission of class behind an ideology of individual effort and desert. Many variants of this view have developed around different conceptions of the assets which schools provide to those bound for economic and social privilege, but their recommendations for practice seem invariably to follow Gramsci’s vision of offering whatever resistance to the dominant ideology one can, in whatever institutional setting one can (see Gramsci 1971).

The most recent work in the Marxist tradition attempts to overcome its preoccupation with class stratification, by emphasizing the importance of other dimensions of social cleavage and oppression, such as race, gender and sexual orientation. A related feminist criticism of liberal educational theory and reform, which bears importantly on the care and upbringing of children, is that they have opened up greater opportunity for women to choose traditionally male paths in life, but have done little to elevate domestic work or prepare anyone to do it well (see

Feminist political philosophy).

7 Philosophy of law and education policy

In philosophy of education there are two kinds of work which involve a direct concern with law and draw significantly upon work in the history and philosophy of law. One addresses the general relationships between law and education, the other treats educational issues as problems of public policy whose resolution may be aided by legal argument and reform.

Ancient Greek thought was acutely attuned to questions about the relationships between law and education, and understood both that compliance with law must rest for the most part in an informed acceptance of its demands, and that the laws themselves and all the institutions of a city are educative and must be so regarded to ensure civic well-being. The re-evaluation of these views is evident in Curren's examination of the role of education in the foundations of just law (1995b), in connection with the ideal of rule by consent, and in the work of Sandel (1996) and other communitarians who have reasserted the claim that national policy and law should be shaped by a sensitivity to their educative import. This latter development is particularly important for educational philosophy, inasmuch as there are compelling reasons to think that schooling is not the whole of education, and that its prospects for success are limited by the broader educational forces in a society.

Education is an important arena of public policy debate, and an appropriate though underdeveloped object of philosophical public policy studies. Some of the most important topics of current discussion are educational equality, freedom of speech and religion in government-run education, proposals to create arrangements which would allow parents a choice of schools at the public expense, and school safety and security. These debates bring a consideration of common law principles and fundamental constitutional rights to bear on some of the issues at stake in debates about liberal and democratic education.

Debate over educational equality has focused on alternative conceptions of its form, the educational goals it should be concerned with, and the principles which demand it. Is full equalization the appropriate aim, for instance, or is the relative equality inherent in assuring that all students reach some specified threshold acceptable? Or should one only be concerned, as the courts of the USA are, to ensure that race, native language, learning disabilities and other 'suspect' factors are not barriers to equal educational opportunity? With regard to the justification of equality (see Equality), does the principle of 'equal protection' in the free enjoyment of fundamental political rights provide grounds for insisting on equality, as some, including Gutmann (1987) and Curren (1995a), have argued?

An important line of argument regarding children's rights begins with the conviction that the free speech rights of adults are meaningless if the state can control through education what one thinks as a child. If this is correct, then one might conclude that inculcation of community values beyond a core of essential civic commitments is a breach of fundamental rights. One might also conclude, as Arons (1986) does, that taking freedom of speech and religion seriously requires that parents be provided with a financially feasible choice among schools. An important issue in the philosophy and policy of higher education at present, is how constitutional protection of free speech should be understood to apply to attempts to draft speech codes to suppress racist 'hate speech'.

A debate which invokes common-law principles, rather than constitutional ones, is how we should understand the framework of fundamental legal principles bearing on the school's responsibility for the safety of students. How should one regard the elements of sovereign immunity to liability still present in the legal systems of common-law countries, given the role of compulsory attendance laws in placing children in a position of danger, if school personnel fail to provide adequate security against assault by third parties?

8 Philosophy of science

In order to teach a subject with sensitivity to its epistemic structure, teachers must grasp and be guided by the same kind of understanding which philosophers of science, mathematics, history or economics aim at - that is, a secure (if nontechnical) sense of the methods of discovery or investigation, of the methods and logic of confirmation, and of the forms of explanation and theory which define it as a mode of inquiry, and they must attend to these in both teaching and evaluating students. Philosophy of science in particular has been called into service in efforts to reshape pedagogy, curriculum and methods of assessment, though the lessons drawn could be applied in the teaching of other subjects as well.

An international ‘crisis’ in science education was declared in the 1980s in a series of reports citing dismal levels of both learning and interest in science, and further concern about the inadequacy of science instruction has been generated since then by neo-romantic attacks on science by postmodernists and some feminists. Government calls for revision of science curricula have become more receptive to the idea that students should not only learn science, but learn *about* science, giving encouragement to the idea that introducing history and philosophy of science into the science curriculum would give students not only a more accurate appreciation of science as an enterprise, but a far more engaging one as well.

Two important related topics in current debates about science instruction are constructivism and multiculturalism. Constructivists promote ‘discovery’ learning in science in the belief that scientific thinking develops naturally in children, a belief rooted in a form of empiricism according to which science finds order in experience, and (in the radical versions of constructivism) has access to nothing beyond immediate experience. Versions of relativism originating in selective readings of Kuhn’s work have also become pervasive in educational theory and found their way into proposals for multicultural curricula which would present ethno-sciences as no less rationally confirmed than Western science. Matthews (1994) and others have responded with observations about the distinctiveness of Western science, reminders of Kuhn’s insistence that science *is* rational (though not in a way that can be adequately represented as rule following), and by identifying the empiricist and positivistic premises relied upon by constructivists, even as they denounce positivism (see Kuhn, T.).

Philosophers of education have also made use of work in philosophy of science in offering methodological critiques of social science research in education, and have relied on models of explanation drawn from action theory and philosophy of the social sciences in evaluating and offering alternatives to the explanatory models underlying educational critiques and policy proposals. Green (1980) has been among the most ambitious in this regard in developing what amounts to a rational-choice model of the dynamics of educational systems.

9 Philosophy of mind, language and psychology

It is widely assumed within the educational research community that psychology, cognitive science, psychometrics and social learning theory have largely displaced philosophy from its historical role in formulating theories of the mind, language and human development, and determining what implications (if any) those theories have for educational practice (see Cognitive development; Learning). Nevertheless, at least two roles related to this empirical aspect of educational theory remain appropriate for philosophy, one foundational and critical, the other interpretative and synthetic.

Gilbert Ryle gave encouragement in *The Concept of Mind* to the possibility of a ‘philosophy of learning’, but the analyses of mental concepts which this inspired in the 1950s and 1960s have given way more recently to interest in the foundations and adequacy of the bodies of psychological and measurement research which educational researchers have looked to for guidance in the conduct of educational practice. Behaviourist learning theory and cognitive and moral stage theories have been subjected to critical scrutiny by a number of philosophers. Wren (1982) has examined social learning theory and found its accounts of self-regulation inadequate. Block and Dworkin (1974) have produced a notable critique of ‘general intelligence’ as a theoretical construct and identified deficiencies in the validation of IQ tests as a measure of it. Norris (1995) and others have contributed in a variety of ways to conceptual, experimental and development efforts pertaining to validity, test formats and the measurement of critical and ‘higher-order’ thinking in classroom and standardized tests of achievement.

Even when psychological findings can be accepted at face value, however, their relevance to educational practice can only be settled by recourse to a theory of education concerned with the kinds of persons we should want students to become. A psychological theory is not itself such a theory, despite the recent dominance of psychology in educational studies. There remains the interpretive and synthetic task of building a cogent educational theory, drawing on whatever facts and practical know-how may be available, which a philosopher is as well-equipped as anyone to undertake. It is a task as important as it is difficult, and if the results of past efforts often fall short, both philosophically and practically, that is all the more reason for capable philosophers to turn their attention to it.

Edwards, Jonathan (1703-58)

Jonathan Edwards' work as a whole is an elaboration of two themes - God's absolute sovereignty and the beauty of his holiness. God's sovereignty is articulated in several ways. Freedom of the Will (1754) defends theological determinism. God is the complete cause of everything that occurs, including human volitions. Edwards is also an occasionalist, idealist and mental phenomenalist. God is the only real cause of events. Human volitions and 'natural causes' are mere 'occasions' upon which God produces the appropriate effects. Physical objects are collections of sensible 'ideas' of colour, shape, solidity, and so on, and finite minds are collections of 'thoughts' or 'perceptions'. God's production of sensible ideas and thoughts in the order which pleases him is the only 'substance' underlying them. God is thus truly 'being in general', the 'sum of all being'.

The beauty or splendour of God's holiness is the principal theme of two late works - End of Creation *and* True Virtue *(both published posthumously in 1765). The first argues that God's end in creation is the external manifestation of his internal splendour. That splendour primarily consists in his holiness and its most perfect external expression is the holiness of the saints, which mirrors and depends upon it.* True Virtue *defines holiness as 'true benevolence' or 'the love of being in general' ([1765b] 1957-, vol. 8: 546), and distinguishes it from such counterfeits as rational self-love, instincts like parental affection and pity, and natural conscience. Since beauty is defined as 'agreement' or 'consent' and since true benevolence consents to being in general, true benevolence alone is truly beautiful. Natural beauty and the beauty of art are merely its image. Only those with truly benevolent hearts, however, can discern this beauty.*

Edwards' projected History of Redemption would have drawn these themes together, for it is in God's work of redemption that his sovereignty, holiness and beauty are most effectively displayed.

1 Life

Edwards was born into a family of Congregationalist clergymen in East Windsor, Connecticut in 1703. He entered Yale in 1716, where he read Locke and Newton and began 'The Mind' (1829a) and 'Natural Philosophy' (1829b). In 1725 the church in Northampton chose Edwards to succeed his grandfather, Solomon Stoddard. The most notable events of his tenure were the revivals of 1734 and 1740, the latter of which came to be known as the 'Great Awakening'. Edwards' defence of the revivals and criticisms of their excesses culminated in his first major treatise, the *Religious Affections* (1746). Worsening relations with his congregation came to a head in a dispute over qualifications for church membership, with Edwards rejecting the less rigorous standards of his grandfather and insisting on a public profession of saving faith. He was dismissed in 1750 by a margin of one vote. Refusing invitations to pulpits in North America and Scotland, Edwards retreated to the Indian mission at Stockbridge, where he completed his last major works - *Freedom of the Will* (1754), *Original Sin* (1758), *End of Creation* and *True Virtue* (both published posthumously in 1765). Edwards accepted an appointment as President of the College of New Jersey (now Princeton) in 1757. He died from smallpox in 1758, less than four weeks after his arrival.

2 Theological determinism

Edwards believed that indeterminism is incompatible with our dependence on God and hence with his sovereignty. If our responses to God's grace are contra-causally free, then our salvation partly depends on us and God's sovereignty is not 'absolute and universal'. *Freedom of the Will* is Edwards' defence of theological determinism. He first attempts to show that indeterminism is incoherent. For example, he argues that by 'self-determination' the indeterminist must mean either that one's actions (including one's acts of willing) are preceded by an act of free will or that one's acts of will lack sufficient causes. The first leads to an infinite regress while the second implies that acts of will happen accidentally. Edwards also contends that indeterminism is inconsistent with ordinary moral concepts. If, for instance, the necessity of sinning wholly excuses, then a bias to sin should partially excuse. But it does not; a person who acts from settled habits of maliciousness is deemed 'so much the more worthy to be detested and condemned' ([1754] 1957-, vol. 1: 360). Since indeterminism implies that necessity excuses, it is inconsistent with the way we attribute blame.

Edwards' principal reasons *for* theological determinism are God's sovereignty, the principle of sufficient reason (which requires that everything that begins to be have a complete cause), and God's foreknowledge (see

Omniscience §3). God's foreknowledge is discussed at length. Call a decision I make at time t_n 'D'. God is omniscient and has therefore always believed that D occurs at t_n. Since God cannot be mistaken, the occurrence of D at t_n is entailed by his believing at some earlier time t_{n-m} that D occurs at t_n. But God's forebelief is past (in relation to t_n); therefore, it is 'now necessary' in the sense that nothing can be done at t_n to alter it. Now what is entailed by a necessary fact is itself necessary. Hence, D could not fail to occur at t_n. The conclusion cannot be evaded by appealing to God's timelessness and denying that God's forebeliefs precede their objects. For even though God's forebeliefs may be timeless, divinely inspired prophecies are not. Yet divinely inspired prophecies are necessarily connected with the acts of will they foretell and are clearly past (and hence necessary) in relation to them. *Freedom of the Will* concludes by arguing that necessity is not incompatible with the ascription of praise and blame or with moral responsibility. We are responsible for our actions in the ordinary sense when we do what pleases us, and determinism does not deny that we often act as we please. And though God and Christ necessarily act for the best, their actions are eminently praiseworthy.

3 Idealism, mental phenomenalism, occasionalism and views on identity

Edwards' idealism, mental phenomenalism and occasionalism provide a philosophical interpretation of the doctrine of God's absolute sovereignty. If Edwards is correct, God is the only true substance and the only true cause.

True or real causes meet three conditions: (1) they cannot exist at different times or places from their effects; (2) they are total causes, in that nothing else is needed for their effects; and (3) they necessitate their effects. Now God is spatially and temporally omnipresent; nothing is separated from him by spatial or temporal distance. Furthermore, his activity is a necessary and fully sufficient condition for the occurrence of any spatiotemporal effect. Finally, God's will is necessarily effective. His will, therefore, is a true cause. Nothing else meets these conditions. Hence, God is the only real cause. Apparent causes (for example, striking a match) are simply the *occasions* upon which God produces effects (for example, the match's ignition) according to 'established methods and laws' (see Occasionalism).

In an early paper ('Of Atoms') Edwards argued that the concept of a material substance underlying solidity, resistance and other physical properties is either empty or denotes God's causal activity. If material substance were real, it would be something which 'subsisted by itself, and stood underneath and kept up solidity and all other [physical] properties' ([1829b] 1957-, vol. 6: 215). God alone meets these conditions and is therefore the only 'substance' underlying physical properties. Deploying arguments analogous to (but apparently uninfluenced by) Berkeley's, Edwards further argues that a 'body is nothing but a particular mode of perception' and that 'the material universe exists only in the mind' ([1829a] 1957-, vol. 6: 368; 1957-, vol. 6: 398) (see Berkeley, G. §§3, 6-7).

Edwards' mental phenomenalism is a natural extension of his occasionalism and views on material substance. God is the only real cause of 'thoughts' or 'perceptions'. If a substance is what 'subsists by itself', 'stands underneath' and 'keeps up' a set of properties, then the concept of mental substance too is either empty or denotes God's causal activity. A mind, therefore, 'is nothing but a composition and series of perceptions [mental events]… connected by… laws' ([1829a] 1957-, vol. 6: 398). Mental and physical substance are thus God's producing mental events and their objects (sensible ideas or 'sensations') 'according to… methods and laws' which he has freely established ([1829a] 1957-, vol. 6: 344).

God's sovereignty extends to criteria of identity. 'Species' (kinds or natures) are the ways we classify things. But our classifications depend on our needs and interests, and on the character of the world we live in. In determining these things, God has thus determined what counts as a 'species' or kind. Now criteria of identity are determined by a thing's nature. God, therefore, is the ultimate ground of these criteria (and hence can if he wishes treat Adam and his posterity as one thing, holding the children responsible for the sin of their progenitor).

4 God as being in general

As the only true substance and only true cause, God is 'being in general'. He 'is the sum of all being and there is no being without His being. All things are in Him and He in all' (1955: 87). Edwards does not mean that God is the power of being or being as such rather than an omniscient mind and omnipotent will. God 'is properly' a

necessarily existing 'intelligent willing agent, such as our souls, only without our imperfections, and not some inconceivable, unintelligent, necessary agent' ([1957] 1957-, vol. 13: 452).

True Virtue associates being with capacity or power and asserts that 'degree of existence' is a function of 'greater capacity and power' ([1765b] 1957-, vol. 8: 546). 'Miscellany 94' (1890) assimilates perfect entity and perfect activity. 'An Essay on the Trinity' (1903) identifies God's perfect activity with his outflowing love or holy will. Other passages identify entity with mind or 'perceiving being'. The drift of these scattered observations is an identification of being with mind in action and of degree of being with degree of consciousness and the comparative perfection of the activity in which it is engaged. Because God's power and consciousness are unlimited, so too is his being.

In speaking of God as 'being in general', Edwards means more than that finite beings are totally dependent on God for their existence and properties. Because he is the only true substance and only true cause, created beings are no more than God's 'images' or 'shadows'. God is the 'head' of the system of beings, its 'chief part', an absolute sovereign whose being, power and perfection are so great 'that the whole system of created beings, in comparison of Him, is as the light dust of the balance' (1955: 142). 'Being in general' thus refers to the system of beings - principally to God but to 'particular beings' as well in so far as they depend upon and reflect him.

5 God's end in creation

End of Creation defines God's glory as 'the emanation and true external expression of God's internal glory and fullness'. It includes (1) 'the exercise of God's perfections to produce a proper effect', (2) 'the manifestation of his internal glory to created understandings', (3) 'the communication of the infinite fullness of God to the creature' and (4) 'the creature's high esteem of God, love to God, and complacence and joy in God; and the proper exercises and expressions of these' ([1765a] 1957-, vol. 8: 527).

The first and third 'parts' of God's glory are not ontologically distinct since the principal effect of God's exercise of his perfections is 'his fullness communicated'. And the third includes the second and fourth, as God's internal fullness or glory is the 'fullness of his understanding consisting in his knowledge' of himself 'and the fullness of his will consisting in his virtue and happiness'. God's 'external glory… consists in the communication of these', that is, in bringing it about that 'particular minds' know and love God and delight in him. One through four are thus 'one thing, in a variety of views and relations' ([1765a] 1957-, vol. 8: 527).

Edwards never doubted that God's end or aim must be that which is supremely good and excellent, namely himself. But he also thought that the essence of goodness is the communication of good for its own sake and that this implies that the creature's happiness is God's ultimate end. *End of Creation* reconciles these convictions by including human happiness (which consists in knowing and loving God, and rejoicing in him) in God's ultimate end, namely the communication of his internal glory '*ad extra*'.

Now God is primarily glorious for his holiness and his will is holy because it exhibits true benevolence - the love of being in general in which 'true virtue' consists. The communication of his internal glory therefore principally consists in the holiness of the saints (the elect), which is identical with their love of being in general, that is, of God and their neighbour.

6 Ethics

Edwards' reflections on ethics culminate in *True Virtue* (1765b). True virtue's aim is the general good. Those who love the general good, however, also prize the disposition that promotes it. Truly benevolent people thus love two things - being and benevolence. But truly virtuous people not only value benevolence because it promotes the general good; they also relish it for its own sake. Hence, while virtue 'most essentially consists in benevolence to Being in general' ([1765b] 1957-, vol. 8: 540), there is a wider sense in which it includes not only benevolence but also a delight or 'complacence' in benevolence's intrinsic excellence or beauty.

It is God that is 'infinitely the greatest being' and 'infinitely the most beautiful and excellent'. True virtue thus principally consists 'in a supreme love to God, both of benevolence and complacence' ([1765b] 1957-, vol. 8: 550-1). It follows that 'a determination of mind to union and benevolence to a *particular person or private system* [whether one's self, one's family, one's nation or humanity], which is but a small part of the universal system of

being… is not of the nature of true virtue' unless it is dependent on, or 'subordinate to, benevolence to Being in general' ([1765b] 1957-, vol. 8: 554).

Things that ordinarily pass as virtue - rational self-interest, such natural instincts as parental affection and pity, and conscience - are counterfeits. These simulacra prompt us to promote the good of others and to approve virtue and condemn vice. But they fall 'short of the extent of true virtuous benevolence, both in… nature and object' ([1765b] 1957-, vol 8: 609). There is no more true virtue in loving others from self-love than in self-love itself. Natural instincts such as parental affection or pity are defective because 'they don't arise from any temper of benevolence to Being in general' ([1765b] 1957-, vol. 8: 610). (Thus I may pity the misfortune of someone whose good fortune would displease me.) Conscience is the product of a power of placing ourselves in the situation of others (which is necessary for mutual understanding), a sense of the natural fitness of certain responses (injury and punishment or disapproval, benefit and approval or reward), and self-love. Placing ourselves in the situation of those we have injured, we recognize that we would resent being treated in the same way and that we are therefore inconsistent in approving of treating others in ways we would not wish to be treated ourselves. The resulting sense of 'inconsistence' or 'self-opposition' makes us 'uneasy' since 'self-love implies an inclination to feel and act as one with ourselves' ([1765b] 1957-, vol. 8: 589).

7 Theological aesthetics

According to Edwards, beauty or 'excellency' 'consists in the similarness of one being to another - not merely equality and proportion, but any kind of similarness…. This is an universal definition of excellency: The consent of being to being' (*[1829a] 1957-, vol. 6: 336*). One who loves others, for example, or wishes them well 'agrees' with them or 'consents' to them. But love's scope can be narrower or wider. Agreement or consent is 'comprehensive' or 'universal' only when directed towards being in general. True benevolence alone, therefore, is truly beautiful. The beauty of a well-ordered society, of the natural fitness between actions and circumstances, 'of a building, of a flower, or of the rainbow' is an 'inferior, secondary beauty' which is a mere image of this. Secondary beauty consists in order, symmetry, harmony or proportion, that is, in 'uniformity in the midst of variety' ([1765b] 1957-, vol. 8: 561-2).

Only God's benevolence is perfect. Hence, God alone is (truly) beautiful without qualification. The fitness of God's dispensations, the harmony of his providential design, and so on, also exhibit the highest degree of secondary beauty. God, therefore, is 'infinitely the most beautiful and excellent' ([1765b] 1957-, vol. 8: 550).

God is also the 'foundation and fountain… of all beauty'. 'All the beauty to be found throughout the whole creation is… the reflection of the diffused beams of that Being who hath an infinite fullness of brightness and glory' ([1765b] 1957-, vol. 8: 550-1). God's world is saturated with beauty - not only the 'harmony of sounds, and the beauties of nature' to which Edwards was especially sensitive but also (and primarily) the beauty of the gospel, of God's providential work in history and of the saints. The saints alone, however, can discern true beauty.

8 The sense of the heart

Because the Holy Spirit dwells in them, the saints love being in general. Their benevolence is the basis of a new 'spiritual sense' whose 'immediate object' is the 'beauty of holiness' - a 'new simple idea' that cannot 'be produced by exalting, varying or compounding' other ideas and that truly 'represents' divine reality ([1746] 1957-, vol. 2: 205, 260; [1765b] 1957-, vol. 8: 622).

Edwards sometimes identifies beauty with the pleasure that holy things evoke in the saints or the tendency they have to evoke it, and at other times with the consent of being to being. His view, however, appears to be as follows. An idea of true beauty is similar to a Lockean idea of a primary or secondary quality. Feelings of spiritual delight are (to use Locke's words) simple 'sensations or perceptions in our understanding' like our ideas of colour or solidity. The tendency holy things have to evoke these ideas in the saints is what Locke calls a 'quality', that is, 'the power to produce those ideas in us' ([1689] 1894, vol. 1: 169). Benevolence is the objective 'mechanism' underlying this power. Like simple ideas of primary and secondary qualities, the spiritual sensation 'represents' or is a 'perception' of its object. Just as 'extension' can refer to the idea, the power or the configuration of matter which is the base of the power, so 'true beauty' can refer to the spiritual sensation, the relevant dispositional property or to benevolence.

Edwards calls the new mode of spiritual understanding a ‘sense’ because the apprehension of spiritual beauty is (1) immediate (non-inferential) and (2) involuntary. Furthermore, (3) it involves relish or delight and (following Locke) being pleased or pained is a kind of sensation or perception. Finally, (4) it is the source of a new simple idea and (as Locke says) all simple ideas come ‘from experience’.

The saints alone are in a proper epistemic position to discern the truths of religion. Only those who are struck with the beauty of holiness can appreciate the ‘hatefulness of sin’, for example, and thus be convinced of the justice of divine punishment and our inability to make restitution. The new sense also helps us grasp the truth of the gospel as a whole. A conviction of the gospel’s truth is an immediate inference from its beauty or splendour.

Edwards’ defence of the objectivity of the new spiritual sense has four steps. (1) Benevolence agrees with the nature of things. The world is an interconnected system of minds and ideas in which the only true substance and cause is an infinite and omnipotent love. Human benevolence is thus an appropriate or fitting response to reality. (2) Benevolence delights in benevolence. Since benevolence is an appropriate response to reality, so too is delight in benevolence. (3) But delighting in benevolence just is perceiving its spiritual beauty. It follows that (4) the saints’ spiritual perceptions are true ‘representations’ of something ‘besides what [is] in [their] own minds’ (*[1765b] 1957-, vol. 8: 622*).

9 *The History of Redemption*

In a letter of 1757 to the trustees of the College of New Jersey, Edwards said that he had long contemplated ‘a great work, which I call a *History of the Work of Redemption*, a body of divinity in an entire new method, being thrown into the form of a history’ ([1829-30, vol. 1: 569-70] 1957-, vol. 9: 62). Edwards’ untimely death aborted the project, but a sermon series delivered in 1739 ([1774] 1957-, vol. 9) which traces the work of redemption ‘from the fall of man to the end of the world’ would have undoubtedly provided its basis. His proposed history would have been the natural culmination of the project begun in *True Virtue* and *End of Creation*. For the redemption is ‘the *summum* and *ultimum* of all the divine operations and decrees’, the manifestation of God’s internal glory in time ([1829-30, vol. 1: 569-70] 1957-, vol. 9: 62). It would have also provided a fitting climax to Edwards’ intellectual career as a whole. For it is in his work of redemption that God most fully displays his sovereignty, holiness and splendour. Whether Edwards’ work would have anticipated modern historiography, as some claim, is more doubtful. For the sermon series is essentially a doctrinal work. (The section on Christ’s earthly ministry, for example, is not a life of Jesus but a discussion of the incarnation and atonement.) Nor does Edwards restrict himself to natural causes, but freely appeals to divine decrees and to typology to explain events. Whatever novelty the sermon series has consists in the rich skein of images by which Edwards connects the events of redemption history and in an emphasis on the objective side of God’s act of redemption; this is comparatively rare in a Puritanism which stressed the redemption’s application. (Edwards treats the subjective side in *Religious Affections*.)

List of works

Edwards, J. (1957) *The Works of Jonathan Edwards*, ed. P. Miller (vols 1-2), J. Smith (vols 3-9) and H.S. Stout (vols 10-), New Haven, CT: Yale University Press, 1957-.(The earlier Dwight edition is a widely available edition of Edwards’ work. Miller *et al.* will supersede earlier editions when completed; the extensive introductions are especially helpful.)

Edwards, J. (1746) *Religious Affections*, in *The Works of Jonathan Edwards*, New Haven, CT: Yale University Press, 1957-, vol. 2.(An analysis of the nature of holy affections and the criteria for distinguishing them from counterfeits.)

Edwards, J. (1754) *Freedom of the Will*, in *The Works of Jonathan Edwards*, New Haven, CT: Yale University Press, 1957-, vol. 1.(A philosophically sophisticated defence of determinism.)

Edwards, J. (1758) *Original Sin*, in *The Works of Jonathan Edwards*, New Haven, CT: Yale University Press, 1957-, vol. 3.(Part 3 (351-433) contains interesting discussions of inherited liability, identity and occasionalism.)

Edwards, J. (1765a) *End of Creation*, in *The Works of Jonathan Edwards*, New Haven, CT: Yale University Press, 1957-, vol. 8, 405-536.(Discusses God’s reasons for creating the world.)

Edwards, J. (1765b) *True Virtue*, in *The Works of Jonathan Edwards*, New Haven, CT: Yale University Press,

1957-, vol. 8, 539-627.(Edwards' major treatise on ethics.)
Edwards, J. (1774) *A History of the Work of Redemption*, in *The Works of Jonathan Edwards*, New Haven, CT: Yale University Press, 1957-, vol. 9.(The sermon series delivered in 1739.)
Edwards, J. (1829a) 'The Mind', in *The Works of Jonathan Edwards*, New Haven, CT: Yale University Press, 1957-, vol. 6, 332-93.(Notes for a proposed treatise on the mind.)
Edwards, J. (1829b) 'Natural Philosophy', in *The Works of Jonathan Edwards*, New Haven, CT: Yale University Press, 1957-, vol. 6, 192-295.(A collection of papers and notes that contains the important 'Of Being', 'Of the Prejudices of the Imagination' and 'Of Atoms'.)
Edwards, J. (1890) 'Miscellany 94', in *The Works of Jonathan Edwards*, New Haven, CT: Yale University Press, 1957-, vol. 13, 256-63.(Edwards' first discussion of the Trinity.)
Edwards, J. (1903) 'An Essay on the Trinity', in *Treatise on Grace and Other Posthumously Published Writings*, Cambridge: James Clarke & Co., 1971, 99-131.(Written in 1730. Edwards' second major discussion of the Trinity.)
Edwards, J. (1817, 1847) *The Works of President Edwards*, ed. E. Williams and E. Parsons, New York: B. Franklin, 1968.(A reprint of the eight-volume 1817 edition and the two supplementary volumes published in 1847.)
Edwards, J. (1829-30) *The Works of President Edwards*, ed. S.E. Dwight, New York: G. & C. & H. Carvill, 10 vols.(A widely available edition of Edwards' work.)
Edwards, J. (1955) *The Philosophy of Jonathan Edwards from His Private Notebooks*, ed. H.G. Townsend, Eugene, OR: University of Oregon Monographs.(Contains philosophically important selections from the 'Miscellanies', a series of over 1,300 entries on philosophical and theological topics begun in 1722.)
Edwards, J. (1971) *Treatise On Grace and Other Posthumously Published Writings*, ed. P. Helm, Cambridge: James Clarke & Co.(Contains papers not included in the collected works, including 'Observations Concerning the Scripture Oeconomy of the Trinity and Covenant of Redemption' (Miscellany 1062).)

Egoism and altruism

Henry Sidgwick conceived of egoism as an ethical theory parallel to utilitarianism: the utilitarian holds that one should maximize the good of all beings in the universe; the egoist holds instead that the good one is ultimately to aim at is only one's own. This form of egoism (often called 'ethical egoism') is to be distinguished from the empirical hypothesis ('psychological egoism') that human beings seek to maximize their own good. Ethical egoism can approve of behaviour that benefits others, for often the best way to promote one's good is to form cooperative relationships. But the egoist cannot approve of an altruistic justification for such cooperation: altruism requires benefiting others merely for their sake, whereas the egoist insists that one's ultimate goal must be solely one's own good.

One way to defend ethical egoism is to affirm psychological egoism and then to propose that our obligations cannot outstrip our capacities; if we cannot help seeking to maximize our own well being, we should not hold ourselves to a less selfish standard. But this defence is widely rejected, because psychological egoism seems too simple a conception of human behaviour. Moreover, egoism violates our sense of impartiality; there is no fact about oneself that justifies excluding others from one's ultimate end.

There is, however, a different form of egoism, which flourished in the ancient world, and is not vulnerable to this criticism. It holds that one's good consists largely or exclusively in acting virtuously, and that self-interest properly understood is therefore our best guide.

1 Definitions of 'egoism'

The term 'egoism' was introduced into modern moral philosophy as a label for a type of ethical theory that is structurally parallel to utilitarianism (see Utilitarianism). The latter theory holds that one ought to consider everyone and produce the greatest balance of good over evil; egoism, by contrast, says that each person ought to maximize their own good. Both theories are teleological, in that they hold that the right thing to do is always to produce a certain good (see Teleological ethics). But the utilitarian claims that the good that one is to maximize is the universal good - the good of all human beings and perhaps all sentient creatures. The egoist, on the other hand, holds that the good one is ultimately to aim at is only one's own (see Good, theories of the).

This way of classifying ethical theories is due to Henry Sidgwick, who regarded the choice between utilitarianism and egoism as one of the principal problems of moral philosophy. In *The Methods of Ethics* (1874), Sidgwick frames the issue in terms that assume that the good is identical to pleasure (a doctrine called 'hedonism') (see Hedonism). He uses 'utilitarianism' for the view that one is to maximize the amount of pleasure in the universe, and holds that the only form of egoism worth considering is hedonistic egoism. Since few philosophers now accept the identity of pleasure and the good, the terms of the debate have changed. 'Egoism' is applied to any doctrine, whatever its conception of the good, that advocates maximizing one's own good.

Often this doctrine is called 'ethical egoism', to emphasize its normative status. By contrast, the term 'psychological egoism' is applied to an empirical hypothesis about human motivation. It holds that whenever one has a choice to make, one decides in favour of the action one thinks will maximize one's own good. It is possible to agree that we are inevitably selfish in this way, but to regard this as an evil element in our nature. Conversely, it is possible to hold that although people ought to maximize their own good, they seldom try to do so. (In the remainder of this entry, 'egoism' will refer to ethical egoism, unless otherwise indicated.)

2 Egoism's treatment of altruism

A defender of egoism need not frown upon attachments to others, feelings of compassion, or beneficent acts. For it is open to the egoist to argue that these social ties are an effective means to one's own ends. For example, it is a matter of common sense that altruistic behaviour - behaviour intended to help others - is often advantageous, when it motivates others to respond in kind (see Reciprocity). What little one loses in simple acts of kindness may be more than compensated when others reciprocate.

Although egoists may argue that benefiting others is generally in one's interests, they give a controversial justification for such beneficence. It is widely agreed that one should at times benefit others for *their* sake

(Aristotle, for example, in *Nicomachean Ethics*, considers this essential to the best kind of friendship). To act for the sake of others is to take their good as a sufficient reason for action. But this is exactly what egoists cannot accept. They hold that ultimately the only justification for acts of beneficence is that they maximize one's own good. Ultimately, one is not to benefit others for their sake, but for one's own. If 'altruism' is used (as it often is) to refer to behaviour that not only benefits others, but is undertaken for their sake, then egoism is opposed to altruism.

3 Arguments for and against

Philosophers have sometimes tried to refute egoism by showing that it contains a contradiction or is in some way self-undermining. The best known attempt is that of G.E. Moore in *Principia Ethica* (1903), but he has had few followers. Instead, Sidgwick's opinion that egoism is rational is generally accepted. But even if one agrees, one may ask whether there are good reasons for choosing egoism over other alternatives. Why must it always be a mistake to sacrifice one's good for the greater good of others? If a small loss in one's wellbeing can produce great gains for others, what is wrong with accepting that loss?

The egoist might at this point take refuge in psychological egoism. Although it is possible to affirm psychological egoism and reject ethical egoism - to agree that by nature we are ultimately self-seeking, and to condemn such behaviour as evil - few philosophers regard this as an appealing mix of theories. For what plausibility can there be in a standard of behaviour that we are incapable of achieving? The egoist may therefore respond to our question 'Why should we not sacrifice our good for the sake of others?' by urging us not to impose impossible standards upon ourselves. We do not in fact make such sacrifices, and should not blame ourselves for being the way we are.

The problem with this strategy is that psychological egoism has come under heavy attack in the modern period. Hobbes (1651) and Mandeville (1714) have been widely read as psychological egoists, and were criticized by such philosophers as Hutcheson (1725), Rousseau (1755) and Hume (1751), who sought to show that benevolence, pity and sympathy are as natural as self-love (see Hobbes, T.; Mandeville, B.; Hutcheson, F.; Rousseau, J.-J.; Hume, D.). Kant held (1788), against psychological egoism, that the rational recognition of moral principles can by itself motivate us and overcome self-love (see Kantian ethics). Perhaps the most influential critique of psychological egoism is that of Butler (1726), who argued that by its nature self-love cannot be the only component of our motivational repertoire (see Butler, J.). He also pointed out that even if we feel gratification when we satisfy our desires, it cannot be inferred that such gratification is the object of those desires. The combined force of these attacks has left psychological egoism with few philosophical defenders.

At this point, an important challenge to ethical egoism should be noticed: although my circumstances, history, or qualities may differ from yours in morally significant ways, and these differences may justify me in seeking my good in preference to yours, the mere fact that I am myself and not you is not by itself a morally relevant difference between us. That my good is mine does not explain why ultimately it alone should concern me. So, if my good provides me with a reason for action, why should not your good, or the good of anyone else, also provide me with a reason - so long as there are no relevant differences between us? The ideal of impartiality seems to support the conclusion that we should have at least some concern with others (see Impartiality). In fact, egoists implicitly accept a notion of impartiality, since they say that just as my ultimate end should be my good, yours should be your good. So they must explain why they accept this minimal conception of impartiality, but nothing stronger. There is nothing morally appealing about excluding all others from one's final end; why then should one do so?

4 An ancient form of egoism

The kind of egoism we have been discussing can be called 'formal', in that it makes no claim about what in particular is good or bad for human beings. It holds instead that whatever the good is, it is one's own good that should be one's ultimate end. This is the conception one arrives at when one begins from Sidgwick's pairing of egoism with utilitarianism, then abstracts from his hedonism. A different kind of egoism, which might be called 'substantive', first proposes a concrete conception of the good, and then urges each of us to maximize our own good, so conceived. It is this form of egoism that flourished in the ancient world. Plato, Aristotle and the Stoics do not accept the formal principle that whatever the good is, we should seek only our own good, or prefer it to the good of others (see Plato; Aristotle; Stoicism). Instead, they argue for a specific conception of the good, and

because the social virtues play so large a role in that conception, they regard self-love not as the enemy of virtue and the larger community but as an honourable motive, once it is developed in the proper direction (see Eudaimonia; Virtues and vices).

Even if psychological egoism is too simple a conception of human nature, it is undeniable that we normally have a deep concern for our own welfare. If self-love is a force that often conflicts with moral duty and inherently resists education, then human beings are necessarily and deeply divided creatures. This is the Augustinian and Kantian picture. By contrast, the dominant strand of ancient ethics proposes a more optimistic conception of the human situation. It does not claim that one should seek one’s own good, come what may for others; rather, by arguing that acting virtuously and acting well coincide, it seeks to undermine the common assumption that at bottom the self must come into conflict with others.

Egyptian cosmology, ancient

Ancient Egypt has left us no systematic philosophy in the modern sense. However, there is abundant evidence that the Egyptians were concerned with all the usual problems of existence. The answers to these questions were mostly expressed through the use of myth, or commentary upon myth. Though complex and polytheistic, Egyptian religion provided a subtle means of commentary upon a range of theological, ethical and psychological questions. The range and quality of Egyptian technical achievements presupposes a degree of theoretical knowledge, some of which has survived and some of which can be reconstructed, either from Egyptian texts themselves, or from commentaries in the classical authors. Until recently much of the latter has been dismissed as inaccurate, but modern scholars are increasingly inclined to agree with the high value which Greek commentators placed on Egyptian thinking.

1 Sources

Although Egyptian civilization lasted for almost thirty-five centuries, many texts survive only in fragments, or are lost completely. The small fraction which has come down to us is biased in favour of royal inscriptions or monumental texts. The loss of temple libraries, which are known to have contained technical manuals and catalogues, is especially unfortunate. The large quantity of administrative texts which survive are of more value to the social and economic historian than to the philosopher. On the other hand, a strong tradition of scribal education existed which has ensured the transmission of ethical and didactic works in some numbers. As a result, the broad principles of Egyptian thinking can be reconstructed with some confidence.

A good starting point can be found in the so-called *Memphite Theology*. In its present form this is a hieroglyphic inscription, now in the British Museum. It is dated to the reign of Shabaqo (*c*.710 BC), although the original text could date from 500 years earlier and a date in the third millennium BC has even been suggested. In the *Memphite Theology*, the god Ptah, patron of Memphis and of craftsmanship, is described as the creator of the world, which he does by means of his heart (the traditional seat of thought and feeling) and his tongue. In other words, the creator first conceptualizes the forms to be created and then brings them into being by means of articulate language.

The Egyptians attached great importance to names. They believed names contained the essence of the object or person to which they referred. They were also drawn to etymologies based on puns. These were considered not to be accidental, but to contain vital information about the meaning and purpose of words. Egyptian dictionaries were based on this principle and the hieroglyphic script itself arises from similar use of paronomasia, or play on words. Creation legends were common in Egypt as in other civilizations, but the sophistication and clarity of the *Memphite Theology* are remarkable. Parallels with the opening of Genesis are occasionally made, although these should be treated with caution.

Similar sophistication can be found unusually in the *Book of the Dead*. This is a mixture of spells, myths and apotropaic formulae (intended to prevent evil), designed to secure the survival of the deceased beyond the divine judgment which awaited them and into the afterlife. Although the ideas underlying the *Book of the Dead* are complex and sublime, the composition itself is not normally considered an intellectual triumph. Chapter 75 of the text contains impressive material which takes the form of a dialogue between the spirit of the deceased, often identified with the god Osiris, and a supreme creator named Atum. The dead man finds eternity incomprehensible because it lacks food and drink, human love and familiar landmarks of time or space. Atum’s reply is that all these have been superseded by the eternal contemplation of his own face, amounting to a communion with his presence beyond physical description. Here too there is evidence of serious questioning about the nature of existence and the problem of comprehending other dimensions of reality.

2 Doctrines

Egyptian religion was complex and its only modern parallel would be Hinduism. A multiplicity of gods was subdivided into local divinities. These were arranged in triads, broadly comparable with human families consisting of god, goddess and child (normally male, but sometimes female). The same gods could rearrange themselves into different families in differing localities. Most gods could be assimilated into the solar deity, which had various names, while some gods combined in pairs for certain functions. The god Osiris was thought of as an earthly

god-king who had undergone death and been restored to immortality in the underworld. In many ways, Osiris and the sun-god are counterparts. This concept introduces us to one of the characteristics of Egyptian thought: the emphasis on duality and the need to reconcile opposing principles. The force which reconciled these opposites was *ma'at*, a concept embracing truth, justice and harmony, and which could be personified as a goddess in its own right.

A similar duality can be seen in the theology of kingship. Unlike the rulers of neighbouring states, the Pharaoh was both divine and human. The divine aspect of the ruler was expressed in the prenomen given to him (or occasionally her) at the coronation. This name was borne by him even after his death, when he became Osiris. His personal name, or nomen, was equally revered, but was not part of his immortal identity. (Conventionally, this duality was expressed in a double title, but wrongly translated as 'King of Upper and Lower Egypt'.) It is possible although not certain that this pattern of thought survived into the early Christian period, where it may have predisposed the Egyptians towards Monophysitism, the belief that the person of Christ has only one nature, which is divine and possesses human attributes.

A corresponding pattern of duality and immanence can be seen in the concept of the *ka*, essentially a birth-spirit similar to the Latin *genius*. However, the idea also encompassed the notion of the immortal essence humans were thought to possess and the individuality which distinguished them. Other living things possessed *kas*, a belief which conveniently allowed offerings of food or flowers to be presented to the gods, who would happily partake of their *kas* while leaving the physical objects to be consumed by the priesthood. However, the *ka* was also dependent on the survival of the earthly body after death. This tenet underwrote the entire death industry characteristic of the culture, although in the main it was concerned with immortality rather than morbidity. There is also a psychological link between the *ka* and the name. In later texts these two terms can be used interchangeably.

Later Neoplatonists, notably Iamblichus, were fascinated by Egyptian religion, at least by the aspects which were accessible. Iamblichus saw the entire system as monotheistic and he and others were convinced that it foreshadowed the Platonic Theory of Forms (see Plato §10). Most Egyptologists have been dismissive of these ideas, although they have begun to gain some credibility over time. Monotheism is compatible with much of what is known about Egyptian gods. The idea itself, and the broad outlines of the theory of Forms, might have been acceptable to an educated Egyptian at the earliest period. The Egyptian would have rejected the exclusive nature of such ideas as the sole explanation of thinking. Those who did try to impose such exclusivity upon Egyptian religion, such as the Pharaoh Akhenaten, were condemned. Some of these ideas, combined with themes from Hellenistic philosophy, resurfaced in the body of texts known as the *Corpus Hermeticum* (second century AD), where they are ascribed to the Graeco-Egyptian divine sage known as Hermes Trismegistos (see Hermetism).

Egyptian technology was impressive as was the thinking which went with it. The formula for the area of a circle, $A = (8/9\ d)^2$, gives an excellent working value for π, and there are textual references to nanoseconds, the dependence of moonlight on sunlight and possibly the speed of light itself. The fact that such things could not be measured did not mean that they could not be envisaged. Astronomical methods of timekeeping were fairly accurate, as was the use of the water-clock. Astrology, however, was a late import from Mesopotamia, although one that soon became thoroughly naturalized.

Egyptian wisdom literature is a genre of its own. Primarily it is concerned with social and ethical problems of some complexity. As the genre developed, there was a growing emphasis away from questions of purely social behaviour and towards the problem of fate and its relation to individual guilt and responsibility. One answer to this dichotomy was to contrast the psychological impact of good behaviour with that of bad, thus internalizing moral responsibility. In a late text, *Papyrus Insinger*, good is externalized and seen as an absolute to be pursued regardless of consequences or the vicissitudes of fortune. Here too the complexity and range of Egyptian writings are seen at their best. Egyptian thought, like Egyptian art and architecture, tolerates diversity and is characterized by both sophistication and simplicity.

Egyptian philosophy: influence on ancient Greek thought

Before the decipherment of hieroglyphics (a process only completed in the 1830s), it was widely believed that many famous Greek philosophers had studied in Egypt and that Greek philosophy was ultimately derived from a lost 'Egyptian mystery system'. This belief was derived in part from ancient sources, which described how certain Greek philosophers had studied with Egyptian priests. The notion that these individual sessions were part of an extensive formal programme of education derives from an historical novel, Séthos (1731), by the Abbé Jean Terrasson. This book, which pretended to be based on lost original sources, offered a detailed portrait of a complex Egyptian university system. It was translated into several European languages and widely popularized in the rituals and mythology of Freemasonry.

The existence of such a formal Egyptian mystery system of education was not confirmed by actual Egyptian sources once they could be read and translated. The myth has been given a new lease of life in revisionist histories of the ancient world composed by writers whose ancestors had been brought to the New World as slaves. These writers sought to show that Greek philosophy was derived from Egyptian philosophy and that what has been recognized as Western civilization stems from Africa. This entry reviews the evidence for these claims and concludes that although the Greeks had great respect for Egyptian wisdom and piety, what has always been known as Greek philosophy derives from the original work of Greeks. It finds moreover that if the Greek philosophers who lived in Ionia were influenced by any outside ideas, these came to them through the monotheistic religions of other peoples living in the Near East.

1 Greek philosophers in Egypt

Nothing in surviving Egyptian literature from the period before the founding of Alexandria in 332 BC resembles the dialectical methods and argumentative structures invented and used by Greek philosophers. Even after Greeks had been living in Egypt for some centuries, Egypto-Greek philosophical treatises, such as those preserved in the Hermetic Corpus, have a declarative format and theological character (see Hermetism). If Greek philosophy were closely dependent on Egyptian models, we would expect to find evidence of parallel texts or direct echoes, as we do in the case of the Roman poets who from early times adapted and quoted Greek sources. However, we do not find this, in Egypt or in any other contemporary civilization, in the area of Greek philosophy. This is not to say that the Egyptians did not possess a profound theology and concept of justice, or that this theology and other wisdom is not impressively expressed in surviving Egyptian literature. It is simply that Egyptian (or Hebrew) wisdom literatures are different in nature from the philosophical writings of Plato and Aristotle. The writings of these philosophers are nontheological in character and reach their conclusions through argument and discussion. Nor is it likely that there was an Egyptian philosophy, similar to Greek philosophy, that is now lost. If there had been such an extensive body of literature some Greeks would have known about it and there would not have been any reason not to acknowledge it. Greeks tended to be so respectful of Egyptian learning that they were eager to refer to it whenever they could. The kind of Egyptian learning to which Plato refers in his works takes the form of wisdom narratives, the kind of moral tales of which we possess Egyptian examples. In the *Phaedrus* and the *Philebus*, Socrates tells a story about the god Theuth's invention of letters. In the *Timaeus* and the *Critias*, Plato's incomplete dialogue, Critias tells the story of Atlantis, which his ancestor Solon learned from an Egyptian priest during his visit to the Egyptian pharaoh Amasis. These stories are not told in the usual question-and-answer dialogue form, but as long didactic narratives almost certainly of Plato's own invention.

The ancient biographers who describe the philosophers' sojourns in Egypt never discuss in detail what philosophical ideas the Greeks might have learned from Egyptian priests. Rather, they imagine that the Greeks acquired from the Egyptians practical learning, often of a scientific nature. In the minds of the biographers, the acquisition of such Eastern wisdom provided a motivation for Greek philosophers to travel to Egypt and to the Near East. Foreign travel also helped to explain why particular philosophers contrived to be distinctive and original. When Thales (sixth century BC) conjectured that the first element was water he could have been drawing on Babylonian mythology, or reflecting on the importance of the river Maeander to his native city of Miletus. But his biographers supposed that he had also seen the most remarkable of all rivers, the Nile. In order to account for the originality of his ideas of mathematics and religion Greek writers assumed that Pythagoras visited Egypt and the Near East before settling in southern Italy. A century after Pythagoras' death, historian Herodotus conjectured

that Pythagoras’ theory of the transmigration of souls, which has no parallel in early Greek thought, had an Egyptian origin. In fact Egyptian notions of the fate of the soul after death are completely different from the Greek. In the first century BC Egyptian priests told Diodorus that Pythagoras shared with the Egyptians the notion that animals had souls. They also claimed that Pythagoras learned about geometry in Egypt, without mentioning anything specific. Both Egyptians and Greeks were interested in geometry and this common interest was seen to be evidence of dependence. Still more was discovered about Pythagoras as time went on. The Greek Iamblichus specifies that Pythagoras spent twenty-two years in Egypt during which time he studied all aspects of Egyptian religion. He was also initiated into all the rites and learned astronomy and geometry. Iamblichus provides no specific information about what he actually learned. Rather, the point of the journey seems to be that he studied whatever it was he learned abroad. Before going to Egypt he visited Syria and after Egypt he studied with the Magi in Babylon. For ancient Greek biographers, foreign study was the most natural and convenient way to account for the originality of Pythagoras’ ideas.

The priests told Diodorus that everything for which these Greeks were admired was brought from Egypt. They said that Greek philosopher Democritus of Abdera (fifth century BC) spent five years studying astrology in Egypt. This connection seems tenuous because the Egyptians were interested in astronomy, the motion of the stars and not in astrology, predictions about human fate that might be derived from astronomical observation. Like many Greek writers Democritus was interested in the causes of the inundation of the Nile. However, according to astronomer Ptolemy (second century AD), Democritus did his research on weather indications in Macedonia and Thrace. Nothing that he is reported to have said suggests that he had a detailed personal knowledge of Egypt.

In the case of other Greek philosophers, interest in the Nile or geometry counts as ‘evidence’ of a visit to Egypt. The priests told Diodorus that the Greek astronomer Oenopides of Chios (fifth century BC) learned from Egyptian priests about the obliquity of the ecliptic of the sun. Diodorus does not indicate and perhaps did not know that the Pythagoreans already knew about the ecliptic before Oenopides discovered it, or that it had been recognized by the Babylonians around 700 BC. Earlier in his account of Egypt Diodorus gives Oenopides’ explanation of the inundation of the Nile. He explained Oenopides’ deduction that the temperature of well water feels warm in the winter and cold in the summer indicating that the Nile’s subterranean waters maintain similar temperatures in the summer when there are no rains in Egypt. Again there is no reason to imagine that Oenopides needed to study in Egypt in order to form this false hypothesis. His reliance on analogy rather than on empirical evidence seems characteristically Greek.

Diodorus reports that the fourth-century Greek philosopher Eudoxus of Cnidus, like Democritus, learned astrology from the Egyptian priests, although it was the Alexandrian Greeks rather than the Egyptians who were interested in that subject. No doubt Eudoxus could have learned geometry in Egypt. However, it was also possible and more likely that he learned the theory of axiomatic mathematics from his teacher the fouth-century Greek philosopher Archytas of Tarentum. In fact nothing in the surviving fragments suggests that Eudoxus had a highly specialized knowledge of Egypt judging from the fragments. He could have learned what he knew from Greek writers like Hecataeus and Herodotus without ever having visited Egypt. None the less, new details about his visit were added as time went on. The priests at Heliopolis showed the Greek geographer Strabo (first century BC) statues of Plato and Eudoxus and pointed out the places where they had studied, although no one was sure how long they had stayed there as there were several different versions of the story. Diogenes Laertius supplies the name of Eudoxus’ Egyptian teacher, saying that while in Egypt Eudoxus shaved his beard and eyebrows like an Egyptian priest and that while there an Apis bull licked his cloak. Egyptian priests understood this to be an omen that he would be famous, but only for a short time. These anecdotes tell us nothing about what Eudoxus studied or did in Egypt. Instead, they portray him as a late antique holy man, in much the same way as Iamblichus described Pythagoras.

In view of the way Plato uses Egyptian lore, the presence of Egyptian tales in his dialogues does not necessarily indicate that he studied in Egypt, especially since the narration of these tales does not require the use of dialectic and argumentation. Plato never says in any of his writings that he went to Egypt and there is no reference to such a visit in the semibiographical *Seventh Letter*. The superficial knowledge of Egypt and vague chronology displayed in his dialogues resemble historical fiction more than history. Anecdotes about his visit to Egypt appear in the work of writers after the Hellenistic period (*c*.300 BC to the mid first century BC). Later biographers added details to the story of Plato’s Egyptian travels in order to provide aetiologies for the Egyptian references in his writings. In a letter purportedly sent by Phaedrus to Plato in Sais, Plato studies the question of the ‘all’ and Phaedrus asks

for information about the pyramids and unusual Egyptian animals. Plato was supposed to have heard from Sechnupis of Heliopolis the story of Theuth told in the *Phaedrus* and Diogenes Laertius says he went to Egypt to study with Egyptian seers.

The Church Father Clement of Alexandria (AD 150-215) suggested that Plato studied in Egypt with the Hermes Trismegistus, or 'thrice greatest Hermes'. But in fact the collection of works attributed to Hermes could not have been written without the conceptual vocabulary developed by Plato and Aristotle. It is deeply influenced by Plato and the writings of Neoplatonist philosophers in the early centuries AD (see Neoplatonism). Plato seems never to have learned from these Egyptian teachers anything characteristically Egyptian, so far as is known about Egyptian theology from Egyptian sources. His notion of Egyptian theology and life remains similar to that of other Athenians. He did not so much change the Athenian notion of Egyptian culture as enrich and idealize it so that it could provide a dramatic and instructive contrast with Athenian customs in his dialogues.

2 The myth of an Egyptian mystery system

The Egyptians had an urgent reason for wanting to assert their priority over the Greeks. In Herodotus' day the country was under Persian domination and then was ruled by Greeks after Alexander's conquest, therefore one of the few remaining ways for them to maintain national pride was through their history. Similar assertions of priority over the Greeks were made by Jews living in Alexandria. These Jews were determined to show that despite being subject to Greeks, they not only understood Greek culture but had provided the inspiration for the authors of the sacred writings and cherished literature of their conquerors' civilization: the mythical Greek singer Musaeus was none other than Moses. Such claims were taken up by the Church Fathers who sought to show that Greek philosophy owed a considerable debt to Hebrew scripture. There was support for the notion of Egyptian influence on Greek thought in the syncretism of the early centuries AD, most particularly in the cult of Isis, which combined Egyptian ritual practices with the Greek notion of *mysteria*, or initiations.

Terrasson drew on these sources (and his own ideas about French Christian education) for his depiction in his novel *Séthos* (1731) of an elaborate series of Egyptian initiations. The process he described inspired the contemporary initiation rituals of Freemasonry and were perhaps parodied in Mozart's opera *Die Zauberflöte*. The belief persists that these fundamentally Greek ideas could have been Egyptian according to revisionist histories of writers who call themselves Afrocentrists. These writers have insisted that Greek philosophy originated in Egypt, although no direct connection can be found between Egyptian wisdom literature and work of writers like Heraclitus, Plato, or Aristotle.

One of the most influential of these writers, Marcus Garvey (1887- 1940) stated that white Europeans had concealed the truth about the priority of Egyptian (or African) culture because of their hostility towards black people. M. Bernal supported these claims in his study *Black Athena* (1987). C.A. Diop in his influential *Civilisation ou Barbarie (Civilization or Barbarism: an Authentic Anthropology)* (1981) sought to show that there was widespread African influence on Western thought. G.G.M. James in *Stolen Legacy* (1954) and his pupil Y.A.A. ben-Jochannan in *Africa, Mother of Western Civilization* (1971) stated that Aristotle stole books from the library at Alexandria, which in fact was not built until after Aristotle's death. Moreover, no other ancient author says that Aristotle went to Egypt with Alexander. Such claims have no more substance than the assertions of the Hellenistic Egyptians and Jews who claimed that the Greeks borrowed all their ideas from their ancestors. There is no evidence that the Greeks stole or borrowed their philosophy from Egypt, or indeed from other peoples, such as the Phoenicians, Hittites, or Medes, with whom they came into contact. However, there was some Egyptian influence on Greek medicine, science and mathematics from the middle of the second millennium BC which continued after the Greeks re-established contact with the Egyptians in the sixth century BC. But, influence cannot be thought of as theft or borrowing and is usually a two-way process. If the early Greek philosophers drew their ideas from any foreign cultures, it was principally from the civilizations of the Near East.

Einstein, Albert (1879-1955)

Albert Einstein was a German-born Swiss and American naturalized physicist and the twentieth century's most prominent scientist. He produced the special and general theories of relativity, which overturned the classical understanding of space, time and gravitation. According to the special theory (1905), uniformly moving observers with different velocities measure the same speed for light. From this he deduced that the length of a system shrinks and its clocks slow at speeds approaching that of light. The general theory (completed 1915) proceeds from Hermann Minkowski's geometric formulation of special relativity as a four-dimensional spacetime. Einstein's theory allows, however, that the geometry of spacetime may vary from place to place. This variable geometry or curvature is associated with the presence of gravitational fields. Acting through geometrical curvature, these fields can slow clocks and bend light rays.

Einstein made many fundamental contributions to statistical mechanics and quantum theory, including the demonstration of the atomic character of matter and the proposal that light energy is organized in spatially discrete light quanta. In later life, he searched for a unified theory of gravitation and electromagnetism as an alternative to the quantum theory developed in the 1920s. He complained resolutely that this new quantum theory was not complete. Einstein's writings in philosophy of science developed a conventionalist position, stressing our freedom to construct theoretical concepts; his later writings emphasized his realist tendencies and the heuristic value of the search for mathematically simple laws.

1 Life

Albert Einstein was born in Ulm in southern Germany. He entered the Federal Polytechnical School in Zurich, Switzerland, in 1896 to study physics, after failing the entrance exam the previous year. Upon completion of his studies in 1900, he was unable to find an academic position. Having renounced German citizenship in 1896, he acquired Swiss citizenship in 1901. From 1902 to 1909 he worked as a patent examiner in Bern. He then moved rapidly through a series of academic positions in Zurich and Prague. Finally in 1914 Einstein moved to a prestigious professorship without teaching obligations at the University of Berlin and also to the directorship of the new Kaiser Wilhelm Institute for Physics. In 1919, observations of the solar eclipse provided confirmation of his general theory of relativity. The success was trumpeted in the popular press and Einstein became an unwilling celebrity. In 1922, he was awarded the Nobel Prize. After 1920, Einstein became known as an advocate of cultural Zionism, also a socialist and (until the rise of Hitler) a pacifist. After fleeing Germany, from 1933 until his death he was at the Institute for Advanced Study in Princeton, New Jersey, adopting citizenship of the USA in 1940.

2 Special relativity

Classical electrodynamics posited the ether as a medium for carrying light and other electromagnetic waves (see Maxwell J.C. §2; Electrodynamics; Optics §§1, 4). Einstein based his 1905 special theory of relativity on the conviction that the state of rest of this medium was superfluous and could be eliminated from an otherwise unaltered electrodynamics by revising classical notions of space and time. These revisions were developed as the consequences of two postulates: the principle of relativity, which required the equivalence of all uniform or inertial states of motion, and the light postulate, which required that the speed of light remain the same constant, independent of the motion of the source, for observers in any inertial motion.

At first, Einstein's two postulates seemed incompatible. As an observer proceeds through a sequence of ever-faster inertial states of motion, the observer's speed comes closer to that of light. However the light postulate requires that they would see no reduction in the speed of light. Einstein showed that the postulates are compatible if rods and clocks do not behave classically when they move close to the speed of light. Similarly, he showed that no material system could be accelerated up to the speed of light. As the system approaches that speed its inertial mass would increase without limit, precluding further acceleration. The mass gained is proportional to the energy of motion and provides one example of the inertia of energy, a result that became famous under the rubric '$E = m\mathrm{c}^2$'.

In his celebrated 1905 analysis, Einstein explained the apparent incompatibility of the postulates as resulting from an arbitrary conception about the simultaneity of distant events. He described a procedure involving light signals

that would by definition synchronize distant clocks. From this definition and the postulates of his theory, Einstein showed that inertially moving observers in relative motion must disagree over which distant events are simultaneous, in contradiction of classical expectations (see Relativity theory, philosophical significance of §§1-3).

3 General relativity

Einstein's general theory of relativity is a relativistic theory of gravitation extending Minkowski's spacetime formulation of special relativity (see Spacetime §2). Its principal novelty is that gravitational fields are not represented as entities like electric fields distinct from the background spacetime. Rather they appear as curvature in the background spacetime geometry. Since Einstein's theory relegated gravitation to this background structure, it could readily account for the most distinctive property of gravitation: the trajectories of bodies in free fall are essentially independent of their masses and internal constitutions.

The theory agrees observationally with Newtonian theory almost exactly in common domains. Marked differences emerge only in very strong gravitational fields or on cosmic scales. Early empirical successes of the theory depended on very small effects: minute deviations in the motion of the planet Mercury from that expected classically, a small deflection of starlight grazing the sun and the slight reddening of light from a massive star due to the gravitational slowing of the atom-clocks emitting the light.

Einstein's development of the theory over the period 1907-15 was inspired by the hope that a relativistic theory of gravitation might extend the principle of relativity to acceleration. He hoped the final theory would satisfy a principle he attributed to Ernst Mach: inertial forces acting on accelerating bodies are not due to acceleration through space but to an interaction with all other masses (see Relativity theory, philosophical significance of §6). He also postulated the principle of equivalence, which required that the inertial field of uniform acceleration is equivalent to a homogeneous gravitational field. While Einstein's general theory remains without serious challenge as a relativistic theory of gravitation and cosmology, debate continues over all his heuristic principles.

General relativity is 'generally covariant': it employs arbitrary spacetime coordinates. From 1913 to 1915, on the basis of his 'hole argument', Einstein had doubted that such freedom was physically admissible. He answered these doubts with the 'point coincidence argument'. It supposed that the physical content of his theory was fully exhausted by a catalogue of spacetime coincidences, which remain unaltered under arbitrary changes of coordinate system. As early as 1917, Erich Kretschmann objected that general covariance cannot express a generalized principle of relativity since, under the suppositions of the point coincidence argument, any spacetime theory can be recast in a generally covariant form (see Relativity theory, philosophical significance of §4).

One of Einstein's earliest applications of his new theory was his 1917 cosmological model. Its spatial geometry is spherical, so that space has a finite volume and no edge (see Cosmology §3). Einstein's motivation in devising the model was to satisfy Mach's principle, which he felt was violated by stipulating the limiting cosmic geometry at the infinity of space. From the 1920s until his death, Einstein's work on general relativity was increasingly absorbed into his attempts to produce a unified field theory which would treat not just gravitational but also electromagnetic fields geometrically.

4 Quantum theory: early contributions

By 1905 Einstein was convinced of the failure of classical electrodynamics to account for black body radiation, and blamed the wave picture of radiation. His light quantum hypothesis proposed that high-frequency heat radiation behaves thermodynamically as though its energy were spatially localized in quanta whose size depends on Planck's constant. This hypothesis was at the heart of his Nobel prize-winning explanation of the photo-electric effect. The following year, Einstein treated the non-classical behaviour of specific heats at low temperatures with a similar assumption (implicit in Planck's work of 1900) of discreteness for the energy levels of atoms (see Planck, M.).

Einstein never integrated these discontinuities into a coherent theory. Such a theory could not merely replace the wave picture by a particle view, for, in 1909, he had demonstrated that both wave and particle views together were required for a complete account of radiation fluctuations. His 1916 theory of the emission and absorption of radiation was largely independent of the classical picture. It associated momentum as well as energy with the

quanta and introduced stimulated emission, which governs the operation of lasers. His last contribution, before the quantum revolution of 1925-7, was to treat radiation as a quantum gas of indistinguishable particles by means of Einstein-Bose statistics.

Throughout, Einstein employed statistical methods, even representing emission and absorption of radiation as random processes. Yet he never broke with his belief that his treatment was defective since ‘it leaves the time and direction of elementary processes to "chance"’.

5 Quantum theory: critique of the standard interpretation

Einstein reacted strongly against complementarity, the positivist interpretation of the new quantum theory that became standard (see Bohr, N.; Logical positivism §4; Heisenberg, W.), in particular to its indeterminism and irrealism. Einstein felt that no essentially statistical theory could be fundamental in physics (his determinism) and that every fundamental theory should allow one to describe individual objects and processes independently of acts or conditions of observation (his realism). Moreover, he thought that the collapse of the quantum wave function introduced a kind of non-local action that could not be reconciled with relativity and that one could not recover classical mechanics as a suitable limiting case of quantum mechanics.

The impressive empirical success of quantum mechanics led him to envisage a better relativistic theory from which both the quantum theory and ordinary mechanics would emerge as limiting cases. He believed that this new (realist and deterministic) theory would not employ the dynamical variables of mechanics but would require different concepts. Thus Einstein’s vision was not that of a hidden variables’ extension of the quantum theory (see Quantum mechanics, interpretation of §3), as some have supposed. Instead, he worked to build a unified theory of the electromagnetic and gravitational fields that might be the starting point for the new physics. Toward the end of his life, with a unification programme not proceeding well, he may have abandoned his hope for a spacetime (’field’) theory, looking instead to what he sometimes referred to as an ’algebraical physics’.

Einstein’s scientific fame made him the quantum theory’s most important critic. He held that the theory was descriptively incomplete: that the quantum state function describes only ensembles of systems and, at best, provides an incomplete or partial description of the individual case. Einstein argued for this conclusion in a famous paper (’EPR’) co-authored with his then assistants, Podolsky and Rosen (1935). The structure of EPR is complex and has given rise to a whole literature attempting to identify its errors and challenge its assumptions (see Bell’s theorem §1). Ironically, it turns out that EPR was actually written not by Einstein but by Podolsky, and that Einstein himself was critical of Podolsky’s text, which he said ’buried’ the main point. In subsequent publications Einstein gave his own versions. One version assumes that spatially separated quantum systems possess ’real physical states’ (separability) and that these states are not immediately influenced by distant events (locality). Another version discharges these twin assumptions by focusing on macroscopic systems, for which separability and locality seem secure. This argument, developed in a correspondence that produced the similar ’cat paradox’ of Erwin Schrödinger, challenges whether the quantum theory can accommodate gross macroscopic events, like an explosion due to radioactive decay (see Quantum measurement problem).

6 Philosophy of science

The founders of Vienna Circle logical empiricism claimed Einstein as a supporter, arguing, for example, that Einstein’s critique of absolute distant simultaneity implicitly assumed an empiricist criterion of meaningfulness (see Logical positivism §2; Vienna Circle §3). Actually, from the 1920s, Einstein distanced himself from the anti-metaphysical tendencies of logical empiricism. Only in the 1960s, when logical empiricism’s influence waned, did a balanced interpretation of Einstein’s philosophy of science begin to emerge.

Einstein acknowledged Mach’s influence, especially Mach’s example of the historical and critical analysis of received scientific concepts. But from his early work on statistical physics to his late work on unified field theory, Einstein evinced no doubt about the reality of his underlying physical ontology, often representing proof of that reality as his aim, as in his claim that his work on statistical physics and Brownian motion aimed to establish the reality of atoms and molecules.

Einstein’s realism is not, however, the scientific realism of the later twentieth century, nor the convergentist realism of Peirce or Popper (see Scientific realism and antirealism §1). Einstein’s mature philosophy of science

combines a working physicist's realism with Duhemian underdetermination and conventionalism (see Duhem, P.M.M. §4). For Einstein, there is, in principle, no unique determination of theory by empirical evidence, although, in practice, theory choice seems uniquely determined. Because of this underdetermination in principle that Einstein believed pervaded all physical theory, he held that scientific theories are 'free creations of the human intellect', whose predictions must conform to empirical evidence. After the early 1930s, Einstein's rationalist sentiments grew, for he increasingly viewed mathematical or logical simplicity as a guide in choosing among empirically equivalent theories, although he doubted that the relevant sense of simplicity could be precisely defined since it involved 'a reciprocal weighing of incommensurable qualities'. How an underdetermined deep ontology can be considered 'real' is clarified by the recognition that, for Einstein, realism was less a general semantic thesis about the interpretation of all theories and more a demand that spatio-temporal theories satisfy a few, specifically physical, requirements, chiefly determinism and separability.

Einstein's conventionalist realism was refined during the 1920s as he, Schlick and Reichenbach sought to construct a new empiricism opposing the Neo-Kantianism of thinkers like Ernst Cassirer, who tried to save Kant's doctrine of the a priori in the face of general relativity's assertion that the global geometry of spacetime is non-Euclidean. Einstein disputed Schlick and Reichenbach's declaration that only coordinating definitions are conventional, arguing that the coordinating definition- empirical proposition distinction was arbitrary (see General relativity, philosophical responses to).

One of Einstein's most original contributions to scientific methodology was his distinguishing between 'principle theories' and 'constructive theories'. The former are based upon well-confirmed high-level empirical generalizations, like the light and relativity principles in special relativity, or the first and second laws of thermodynamics, which function as regulative principles constraining the choice of constructive models. Ultimate understanding comes via a constructive theory, but early investigations in new domains will progress more rapidly by first seeking principle theories to guide the search for constructive models.

Electrodynamics

Electric charges interact via the electric and magnetic fields they produce. Electrodynamics is the study of the laws governing these interactions. The phenomena of electricity and of magnetism were once taken to constitute separate subjects. By the beginning of the nineteenth century they were recognized as closely related topics and by the end of that century electromagnetic phenomena had been unified with those of optics. Classical electrodynamics provided the foundation for the special theory of relativity, and its unification with the principles of quantum mechanics has led to modern quantum field theory, arguably our most fundamental physical theory to date.

As James Clerk Maxwell (1831-79) pointed out in the preface to his *A Treatise on Electricity and Magnetism* (1873), the ancients were aware that certain bodies, such as amber, once rubbed, attract other bodies. These and similar phenomena are termed electric after the Greek for amber, *ēlectron*. Similarly, the lodestone has long been known to attract pieces of iron at a distance. These and related phenomena are termed magnetic after Magnesia (Greek, *magnēs*), an ancient city in Asia Minor where the lodestone was found. A full historical background to electrodynamics would include the development of electric circuit theory and of optics (see Optics).

The modern science of electricity and magnetism can be conveniently dated by the publication in 1600 of William Gilbert’s (1540-1603) great work on magnetic and electric phenomena. To him we owe the terms ’electric attraction’, ’electrical force’ and ’magnetic pole’. Gilbert associated electricity with a tenuous effluvium (or vapour) that was liberated from a body by the action of friction. René Descartes (1596-1650) attempted to explain magnetism in terms of vortices in a fluid that surrounded magnets. These ideas were consonant with a corpuscular theory of light and the caloric theory of heat. The electric effluvium was even conjectured to be associated with the effect of gravity. Such a plenum or ether would play a central role in the development of physical theory into the beginning of the twentieth century.

Stephen Gray (d. 1736) and Benjamin Franklin (1706-90) were among those who postulated various qualitative theories based on electrical fluids. Joseph Priestley (1733-1804), using an analogy with Newton’s law of gravitation, suggested an inverse square law of attraction or repulsion between electric charges. Although there were earlier approximate verifications, by 1785 Charles-Augustin de Coulomb (1736-1806) made a fairly accurate direct experimental test of this law, which now bears his name.

A concise mathematical formulation of electrostatic theory was presented in 1812 by Siméon-Denis Poisson (1781-1840). Both he and Pierre-Simon Laplace (1749-1827) recognized that the vector electrostatic force (like the gravitational one) could be calculated from the potential energy of a system of charges. By 1828, the theory of the electric potential had been formalized by George Green (1793-1841). In 1820 Hans Christian Ørsted (1777-1851) discovered a new type of effect that arose when charges were set in motion to produce an electric current. These magnetic effects were soon given precise mathematical formulations by Jean-Baptiste Biot (1774-1862), Félix Savart (1791-1841) and, most elegantly, by André-Marie Ampère (1775-1836). In 1845, Franz Neumann (1798-1895) discovered a vector potential function for the magnetic field. Action at a distance remained the dominant mode of thought in this area until the time of Michael Faraday (1791-1867), who introduced the concept of electric and magnetic fields. Faraday’s field, and his 1831 law of electromagnetic induction, formed the basis for Maxwell’s unification of electric and magnetic phenomena. Maxwell’s theory demonstrated that electric and magnetic phenomena are governed by a common set of equations and that optical phenomena are electromagnetic in nature (see Field theory, classical; Maxwell, J.C. §2). Heinrich Hertz (1857-94) contributed significantly to the acceptance of Maxwell’s theory, not only by experimental verification in the 1880s of the electromagnetic nature of light, but also, in the 1890s, with a series of papers that gave a concise presentation of the axioms of Maxwell’s theory and a clear explanation of electromagnetic phenomena by rigorous deduction from those principles. Hertz’s often-quoted dictum that the essence of Maxwell’s theory is the equations themselves would become a fair characterization of the attitude of one school of modern physicists toward theories in general (see Hertz, H.). Even into the twentieth century ‘continental’-style physicists prized theories of generality and mathematical abstractness, whereas models of specific phenomena were favoured in Great Britian.

So dominant had been Newtonian mechanics and the mechanical worldview, that even Maxwell and many of his

contemporaries attempted to underpin electromagnetic phenomena with mechanical models. This was the programme of the electromagnetic ether, brought to its most complete mathematical formulation by Hendrik Lorentz (1853-1928) at the end of the nineteenth century. In fact, electromagnetic phenomena came to play such a central role in physics that, in the early years of the twentieth century, attempts were made to replace the mechanical worldview with an electromagnetic one, whereby mechanical properties such as mass were accounted for in terms of electromagnetic properties such as charge. It was out of these foundational struggles in electrodynamics that Albert Einstein's special theory of relativity emerged in 1905 (see Einstein, A. §2). Subsequent efforts by Paul Dirac (1902-84) to apply the principles of quantum mechanics to electrodynamics led in 1928 to the first formulation of quantum electrodynamics and, through the work of Werner Heisenberg (1901-76) and Wolfgang Pauli (1900-58), which began in 1929, to modern quantum field theory. Electrodynamics was central in quantum field theory coming to the fore and in replacing the old particle-field dualism with the quantum-field ontology (see Field theory, quantum).

Eliade, Mircea (1907-86)

Eliade was educated as a philosopher. He published extensively in the history of religions and acted as editor-in-chief of Macmillan's Encyclopedia of Religion (1987). The influence of his thought, through these works and through thirty years as director of the history of religions department at Chicago University, is considerable.

Eliade's analysis of religion assumes the existence of 'the sacred' as the object of worship of religious humanity. It appears as the source of power, significance and value. Humanity apprehends 'hierophanies' - physical manifestations or revelations of the sacred - often, but not only, in the form of symbols, myths and rituals. Any phenomenal entity is a potential hierophany and can give access to nonhistorical time, what Eliade calls illud tempus *('that time'). The apprehension of this sacred time is a constitutive feature of the religious aspect of humanity.*

1 Life

Eliade was born in Bucharest, Romania. Despite a childhood interest in entomology and botany (which doubtless first attracted his attention to Goethe, a lifelong role model and inspiration), he developed an interest in world literature and was led from there to philology, philosophy and comparative religion. As a youth he read extensively in Romanian, French and German, and around 1924-5 he learned Italian and English to read Raffaele Pettazzoni and James George Frazer in the original.

In 1925 Eliade enrolled at the University of Bucharest, where he studied in the department of philosophy. The influence of Nae Ionescu, then an assistant professor of logic and metaphysics and an active journalist, was keenly felt by the young Eliade and the shadow which fell on the older scholar because of his involvement with the extreme right in interwar Romania has darkened Eliade's reputation.

Eliade's Master's thesis examined Italian Renaissance philosophers from Marcilio Ficino to Giordano Bruno, and Renaissance humanism was one of his major influences when he turned to India in order to 'universalize' the 'provincial' philosophy he had inherited from his European education. Finding that the Maharaja of Kassimbazar sponsored European scholars to study in India, Eliade applied and was granted an allowance for four years. In 1928 he sailed for Calcutta to study Sanskrit and philosophy under Surendranath Dasgupta, a professor at the university there.

He returned to Bucharest in 1932 and successfully submitted an analysis of yoga as his doctoral thesis in 1933, which was published in French as *Yoga: essai sur les origines de la mystique Indienne (Yoga: A Treatise on the Origins of Indian Mysticism)*. This was extensively revised and republished as *Yoga, Immortality, and Freedom* (1958a). As Ionescu's assistant, Eliade lectured on, among other things, Aristotle's *Metaphysics* and Nicholas of Cusa's *Docta ignorantia*. From 1933 to 1939 he was active with the Criterion group, which gave public seminars on a wide range of topics. They were strongly influenced by the philosophy of 'trairism' the search for the 'authentic' in and through lived experience (Romanian, *traire*), which was seen as the only source of 'authenticity'.

After the Second World War, during which he served with the Romanian Legation in the UK and Portugal, Eliade was unable to return to the newly communist Romania because of his connection with the right-wing Ionescu. In 1945 he moved to Paris, where his acquaintance with George Dumézil, an important scholar of comparative mythology, secured him a part-time post teaching comparative religion at the École des Hautes Études at the Sorbonne. From this time on almost all of Eliade's scholarly works were written in French.

At the prompting of Joachim Wach, director of the history of religions department at the University of Chicago, Eliade was invited to give the 1956 Haskell Lectures on 'Patterns of Initiation' at Chicago. These were later published as *Rites and Symbols of Initiation* (1958b). In 1958 Eliade was invited to assume the chair of the history of religions department at Chicago. There he stayed until his death in 1986, publishing extensively and writing largely unpublished fiction. He also launched the journals *History of Religions* and *The Journal of Religion*, and acted as editor-in-chief for Macmillan's *Encyclopedia of Religion* (1987).

2 Thought

Despite his focus on the history of religions, Eliade never relinquished his philosophical agenda. That said, he never fully clarified his philosophy. There has been radical disagreement over his thought, some seeing it as a crucial contribution to the study of religion, and some seeing him as an obscurantist whose normative assumptions are unacceptable.

In *Cosmos and History: The Myth of the Eternal Return* (1954), a book which he was tempted to subtitle *Introduction to a Philosophy of History*, Eliade distinguishes between religious and nonreligious humanity on the basis of the perception of time as heterogeneous and homogeneous respectively. This distinction will be immediately familiar to students of Henri Bergson (§2) as an element of that philosopher's analysis of time and space. Eliade contends that the perception of time as a homogeneous, linear and unrepeatable medium is a peculiarity of modern and nonreligious humanity. Archaic or religious humanity (*homo religiosus*), in comparison, perceives time as heterogeneous; that is, as divided between profane time (linear) and sacred time (cyclical and reactualizable). By means of myths and rituals which give access to this sacred time, religious humanity protects itself against the 'terror of history', a condition of helplessness before the absolute *data* of historical time, a form of existential anxiety.

In the very process of establishing this distinction, however, Eliade undermines it, insisting that nonreligious humanity in any pure sense is a very rare phenomenon. Myth and *illud tempus* are still operative, albeit concealed, in the world of modern humanity and Eliade clearly regards the attempt to restrict real time to linear historical time as finally self-contradictory. He squarely sets himself against the historicism of Hegel (§8).

'The sacred' has also been the subject of considerable contention. Some have seen Eliade's 'sacred' as simply corresponding to a conventional concept of deity, or to Rudolf Otto's *ganz andere* (the 'wholly other'), whereas others have seen a closer resemblance to Émile Durkheim's socially influenced sacred (see Otto, R.; Durkheim, É. §4). Eliade himself repeatedly identifies the sacred as the real, yet he states clearly that 'the sacred is a structure of human consciousness' (1969: i; 1978: xiii). This would argue more for the latter interpretation: a social construction of both the sacred and of reality. Yet the sacred is identified as the *source* of significance, meaning, power and being, and its manifestations as hierophanies, cratophanies or ontophanies accordingly (appearances of the holy, of power or of being). Corresponding to the suggested ambiguity of the sacred itself is the ambiguity of its manifestations.

Eliade states that believers for whom the hierophany is a revelation of the sacred must be prepared by their experience, including their traditional religious background, before they can apprehend it. To others the sacred tree, for example, remains simply a tree. It is an indispensable element of Eliade's analysis that any phenomenal entity could be apprehended as a hierophany with the appropriate preparation. The conclusion must be that all beings reveal, and at the same time conceal, the nature of Being. A reprise of Nicholas of Cusa's 'coincidence of opposites' is evident here, as is a possible explanation of the systematic ambiguity of Eliade's writings (see Nicholas of Cusa §2).

Finally, religion, systematically understood as the apprehension of relative worth conferred through nonhistorical realities (including all abstract and imaginary entities), but revealed and confirmed through historical phenomena, is seen as a unifying human universal. It is characteristic of Eliade's style of writing, both in his fictional and in his academic work, that this conclusion is nowhere clearly stated. Leading assertions are scattered throughout his publications on the history of religions, alchemy, symbolism, initiation, myth and so on inviting his readers either to make an immediate interpretation or to pursue the question further into the thicket of his *oeuvre*.

BRYAN STEPHENSON RENNIE

List of works

Eliade, M. (1954) *Cosmos and History: The Myth of the Eternal Return*, trans. W. Trask, Princeton, NJ: Princeton University Press.(Probably Eliade's most crucial and approachable short work. Contains his analysis of heterogeneous and homogeneous time, and his conception of the 'terror of history' and the ability to 'reactualize' religious time.)

Eliade, M. (1958a) *Yoga, Immortality and Freedom*, trans. W. Trask, London: Routledge & Kegan Paul.(First published in French as *Yoga: essai sur l'origine de la mystique Indienne* in 1933, this informative and scholarly

work analyses yoga as a concrete search for freedom from human limitations.)
Eliade, M. (1958b) *Rites and Symbols of Initiation (Birth and Rebirth)*, trans. W. Trask, London: Harvill Press. (Eliade's 1956 Haskell Lectures at the University of Chicago. His analysis of initiatory themes implies their ubiquity and structure as a symbolic death and rebirth.)
Eliade, M. (1958c) *Patterns in Comparative Religion*, trans. R. Sheed, London: Sheed & Ward.(An attempt to delineate the morphology of the sacred, this is frequently criticized for its cross-cultural and ahistorical approach, which organizes religious phenomena by structural similarities regardless of time or place of origin. A valuable source of data nevertheless.)
Eliade, M. (1959) *The Sacred and the Profane: The Nature of Religion*, trans. W. Trask, London: Harcourt Brace Jovanovich.(Picking up where Otto's *The Idea of the Holy* left off, the sacred is explicated through its relation to its binary counterpart, the profane, and the complex dialectic of the two is outlined.)
Eliade, M. (1960) *Myths, Dreams and Mysteries: The Encounter between Contemporary Faiths and Archaic Realities*, trans. P. Mairet, London: Harvill Press.(Eliade's understanding of myth in the modern world and the mythic prestige of origins, and his analysis, among other things, of the symbolism of ascension, flight, the labyrinth and swallowing by a monster.)
Eliade, M. (1961) *Images and Symbols: Studies in Religious Symbolism*, trans. P. Mairet, London: Harvill Press. (More on symbolism, particularly the symbolism of the centre, knots, shells and pearls. Symbolism and history are discussed, as is method.)
Eliade, M. (1963) *Myth and Reality*, trans. W. Trask, New York: Harper & Row.(The structure of myths. More on the prestige of origins and on the survival of myths and mythic themes in modern thought.)
Eliade, M. (1964) *Shamanism: Archaic Techniques of Ecstasy*, trans. W. Trask, London: Routledge & Kegan Paul.(Long a standard work in the study of shamanism, this is a detailed and valuable source of information on the phenomenon.)
Eliade, M. (1965) *The Two and the One*, trans. J.M. Cohen, Chicago, IL: University of Chicago Press.(An important analysis of the *coincidenta oppositorum* (coincidence of opposites), or binary oppositions, in religious ideas. Androgyny is explored, as are cosmogony and eschatology, the birth and death of the cosmos or worldview.)
Eliade, M. (1969) *The Quest: History and Meaning in Religion*, London: University of Chicago Press.(This attempt at a more methodological work pulls together articles previously published on Eliade's methodological and theoretical presuppositions, including his 'new humanism' and his response to the quest for the 'origins' of religion.)
Eliade, M. (1978) *A History of Religious Ideas*, vol. 1, *From the Stone Age to the Eleusinian Mysteries*, trans. W. Trask, Chicago, IL: University of Chicago Press.(Originally projected as a complete history of religion in one volume, this was an attempt to give Eliade's understanding of the entire history of religion from a unified perspective. It is a useful reference work, potentially readable in its entirety. Many of Eliade's categories survive in this mature work: the terror of history, the *coincidenta oppositorum*, the symbolism of the centre, and the *hieros gamos*, or symbolic heavenly marriage.)
Eliade, M. (1982) *A History of Religious Ideas*, vol. 2, *From Gautama Buddha to the Triumph of Christianity*, trans. W. Trask, Chicago, IL: University of Chicago Press. (See note to volume 1 (1978).)
Eliade, M. (1985) *The History of Religious Ideas*, vol. 3, *From Muhammad to the Age of the Reforms*, trans. A. Hiltebeitel and D. Apostolos-Cappadona, Chicago, IL: University of Chicago Press.(See note to volume 1 (1978).)
Eliade, M. (ed.) (1987) *Encyclopedia of Religion*, New York: Macmillan. (Sixteen volumes of articles on every aspect of religion by leading scholars in the field. Currently the standard reference encyclopedia on religion.)

Eliot, George (1819-80)

George Eliot is the pseudonym of the English writer Mary Ann Evans, whose mind was strongly influenced by the main philosophical currents of the time and who made a distinctive contribution of her own through her critical essays and fiction.

Although George Eliot was early seen to be intellectually gifted, she received little education of an institutional kind after leaving school at 16; from the age of nine, however, she was a prodigious reader, her appetite for learning being strengthened further by the religious conflicts of her youth. After a phase of intense Evangelical devotion she translated Strauss' *Life of Jesus* and turned to humanists such as Spinoza, finding Wordsworth's tempering of pantheism with moral insistence even more congenial (see Strauss, D.F. §1). She was well versed in traditional philosophy and at an early stage spoke of her aspiration that she might 'live to reconcile the philosophies of Locke and Kant'. Her primary concern, however, was with scientific naturalism and its implications. Her spell as assistant editor of the *Westminster Review* from 1851 to 1854 and then as contributor gave her the opportunity to meet and debate with some of the leading writers of the day and to write on topics such as human physiology and critical approaches to the Bible. She worked intimately with Herbert Spencer for a time, respecting him particularly for his acknowledgment that the universe was ultimately unknowable. She admired Darwin's *Origin of Species* but declared herself to be more impressed by 'the mystery that underlies the processes'. She was also fascinated by the associationist psychology of Alexander Bain, its leading exponent, and by the positivism of Auguste Comte, of whom G.H. Lewes, with whom she lived from 1854, was a devoted if critical follower. Her strongest sympathies were perhaps with the intellectual position of Ludwig Feuerbach, who saw religion as essentially an anthropological phenomenon, with Christianity providing the key to the subjective and moral nature of human beings (see Feuerbach, L. §2).

George Eliot thought of herself primarily as an aesthetic teacher, arguing at the same time that 'if such teaching lapses anywhere from the picture to the diagram it becomes the most offensive of all teaching'. Feuerbach's example provided an attractive way of viewing her own role as a novelist, using her longer fictions both as a repository for observations tested by experience and a crucible for the exposition and testing of her own ideas. In *Middlemarch* (1871-2) she carried on this process in a study of provincial life forty years before she was writing, when the implications of the new biblical criticism and developments in the study of physiology were throwing former certainties into doubt, yet also creating exciting prospects. In her most complex fiction, *Daniel Deronda* (1876), current work in physiology and psychology is caught up into the detail of her human observations, while her aspirations towards moral single-mindedness are reflected in the hero's embracing of the Zionist ideal. Her attempts to find a stance for him which could combine the cool rationality of an empiricist with scope for his fiery ardour suggests the ultimate contradiction within which her moral thinking was wrought.

Elisabeth of Bohemia (1618-80)

Elisabeth of Bohemia, Princess Palatine, exerted an influence on seventeenth-century Cartesianism via her correspondence with Descartes. She questioned his accounts of mind-body interaction and free will, and persuasively argued that certain facts of embodiment, the unlucky fate of loved ones, and the demands of the public good, constitute serious challenges to Descartes' neo-Stoic view of the happy life of the autonomous will.

Eldest daughter of the exiled 'Winter King and Queen' of Bohemia, Princess Elisabeth was educated at the Prisenhof in Leiden. In 1644, Descartes dedicated his *Principles of Philosophy* to her, and two years later she attempted to introduce Descartes' work at the German courts. In 1670, as Abbess at Herford, she provided a haven for her correspondent, Anna Maria van Schurman, and the persecuted Labadists. She corresponded and met with Quaker leaders William Penn and Robert Barclay. Near the end of her life, she was interested in the views of Malebranche and the mystical philosopher, Jacob Boehme; she corresponded with Leibniz via her sister Louise, Abbess of Maubuisson in France.

On 6 May 1643, Elisabeth began her correspondence with Descartes by arguing that voluntary motion is unintelligible in terms of Descartes' mechanical philosophy. For, determination of movement is due to (1) the impulsion of the moved object, (2) the manner in which the mover impels the object, and (3) the qualification and figure of the surface of the moving object. (1) and (2) require contact; (3) requires extension. But souls are not extended and contact seems incompatible with their immateriality. Elisabeth urges that we need a more comprehensive definition of 'the soul' than simply a 'thinking thing'; we need to know what other properties the soul has, if we are to make its causal powers intelligible. She notes that while we suppose thought to be essential to the soul, this is difficult to prove in the cases of foetuses and deep faints - a challenge to Cartesianism that the Empiricists subsequently developed. To Descartes' rejoinder that we have a *per se* intelligible primitive notion, known by sense, of how an incorporeal soul can move a corporeal body, Elisabeth - prefiguring the position of Locke and Hume - responds that she has no such notion. She acknowledges that the senses show that the soul moves the body, but she denies that they, any more than imagination or understanding, show *how* this happens. She suggests that there might be unknown properties in the soul - even extension, which might belong to a faculty like sensation.

It is Elisabeth's personal problems, especially 'the weakness of my sex' (poor health due to afflictions of the soul) and the suffering of her family, that lead to discussion of *De Vita Beata (On the Happy Life)* by Seneca. Descartes' neo-Stoic solution requires that happiness depend only on what follows from the will guided by reason. But Elisabeth finds that her passions cannot be *immediately* controlled by her will and this often leads to her body becoming disordered. In addition, there are illnesses that diminish or deprive us of our reasoning power. Finally, regret, 'one of the principal obstacles to happiness', appears unavoidable when attempting to weight one's own goals along with the competing goods of others in society: 'To know all those [goods] about which one is constrained to make a choice in an active life, it would be necessary to possess infinite knowledge' (13 September 1645). Descartes replies that while we cannot know everything, we need only follow certain neo-Stoic principles for a happy life. One such principle is: the infallibility of God's decrees teaches us to accept in good spirit everything that happens to us, since it comes from God. Elisabeth replies that this principle does not help in the case of free decisions of the will; in such cases God's predetermination is not intelligible. She remained puzzled by Descartes' retort that the independence which we feel, which makes our actions sanctionable, is not incompatible with the dependence all things have on God. She argues that it is 'as impossible for the will to be at the same time free and attached to the decrees of Providence, as for the divine power to be both infinite and limited' (30 November 1645). Elisabeth's focus is on the will's liberty of indifference, which Descartes had stressed in his *Principles*, and its incompatibility with determination of any kind.

Some recent commentators have taken Elisabeth's use of her own body and female social role in her criticisms of the privileged, disembodied will as prefiguring contemporary feminist critiques of Cartesianism (Bordo 1998; Harth 1992; Thompson 1983).

Emerson, Ralph Waldo (1803-82)

The American philosopher and poet Ralph Waldo Emerson developed a philosophy of flux or transitions in which the active human self plays a central role. At the core of his thought was a hierarchy of value or existence, and an unlimited aspiration for personal and social progress. 'Man is the dwarf of himself', he wrote in his first book Nature (1836). Emerson resented a dire portrait of humankind's condition: 'Men in the world of today are bugs or spawn, and are called "the mass" and "the herd"'. We are governed by moods which 'do not believe in one another', by necessities real or only imagined, but also,Emerson held, by opportunities for 'untaught sallies of the spirit' - those few real moments of life which may nevertheless alter the whole.

Emerson's lectures drew large audiences throughout America and in England, and his works were widely read in his own time. He influenced the German philosophical tradition through Nietzsche - whose The Gay Science carries an epigraph from 'History' - and the Anglo-American tradition viaWilliam James and John Dewey. Emerson's major works are essays, each with its own structure, but his sentences and paragraphs often stand on their own as expressions of his thought.

1 Life

Ralph Waldo (known to friends and family as 'Waldo') was the fourth of eight children born in Boston to the Reverend William Emerson and Ruth Haskins Emerson. He lost his father to tuberculosis just before his seventh birthday and was brought up by his mother and his father's sister Mary Moody Emerson. After four undistinguished years at Harvard, he became a schoolteacher and studied theology there, preparing for the ministry.

In 1829,Emerson was ordained pastor of the Second (Unitarian) Church of Boston and married Ellen Tucker. Ellen died of tuberculosis in 1831, and the following year Emerson resigned his position on the grounds that he could no longer administer the sacrament of the Last Supper, which he considered a 'dead form'. On Christmas Day, 1832, he set sail for Europe, where he toured Malta, Italy, France, Switzerland, England and Scotland. In Britain, he visited the ageing poets William Wordsworth and Samuel Taylor Coleridge, and the historian and philosopher of culture Thomas Carlyle, who became a lifelong friend.

Soon after his return in November 1833, Emerson gave his first lecture, 'The Uses of Natural History', at the Masonic Temple of Boston, embarking on a career as an orator that would continue for the next half-century. He married Lidian Jackson in 1835 and settled in Concord, Massachusetts, from which he set out on lecture tours through the northeastern United States and later to England (1847-8 and 1872-3) and the American midwest.

Emerson's published works, derived from his lectures and journals, include *Nature* (1836), *Essays, First Series* (1841), *Essays, Second Series* (1844), *Representative Men* (1850), *English Traits* (1856), *The Conduct of Life* (1860) and *Society and Solitude* (1875).

2 Emerson as philosopher

There is no one to whom commentators, philosophers or not, are more apt to *deny* the title of philosopher than Emerson. Most twentieth-century discussions of his work have been by literary critics, with such notable exceptions as John Dewey's 1903 address 'Ralph Waldo Emerson - Philosopher of Democracy' and a series of papers by Stanley Cavell.Emerson is no system-builder in the mould of Descartes, Kant or Hegel, and his use of the essay form - inherited from his hero, Montaigne - corresponds to the radical epistemological and metaphysical openness of his thought: towards the end of his great essay 'Experience', he writes, 'I know better than to claim any completeness for my picture. I am a fragment and this is a fragment of me.'

Emerson has a broadly Kantian outlook, according to which the world is in some way our construction. But like other Romantics, he finds that the 'lenses which paint the world' include our passions: 'Life is a train of moods like a string of beads, and as we pass through them they prove to be many-coloured lenses which paint the world their own hue, and each shows only what lies in its focus.' These moods 'do not believe in one another': each comes with 'its own tissue of facts and beliefs'. In one moment, we find ourselves bound by fate, in another real possibilities open up; in one moment we see a picture or read a book with a sense of adventure and understanding,

in another we cannot see what interested us before. ‘Our life’, Emerson states, ‘is March weather, savage and serene in one hour’.

At the centre of the series of moods lies the self - or, it would be better to say, the problem of the self. Emerson, like Kierkegaard and Nietzsche, finds the existence of the self to be a major issue. If the mass of men are ‘bugs or spawn’ and even the great or representative person is ‘partial,’ then the achievement of a fully developed human self is an enormous task. Emerson presents himself as having undertaken this task in ‘Self-Reliance’ (1841): ‘Few and mean as my gifts may be, I actually am, and do not need for my own assurance or the assurance of my fellows any secondary testimony.’

Emerson’s philosophy is a blend of classical and incipiently ‘postmodern’ or ‘pragmatist’ notions. With its references to the ‘Unity’ or ‘Over-Soul, within which every man’s particular being is contained’, or to ‘the Ideal journeying always with us, the heaven without rent or seam’, Emerson’s writing exhibits a strong Neoplatonic streak. Yet in a world of shifting moods and things that ‘slip through our fingers… when we clutch hardest at them’, Emerson finds no foundations, but only ‘a house founded on the sea’. Even our language, far from reflecting permanent forms, is ‘fluxional’, ‘vehicular and transitive… good, as ferries and horses are, for conveyance, not as farms and houses are, for homestead’. These Neoplatonic and pragmatic tendencies come together in Emerson’s statement that ‘the one thing in the world, of value, is the active soul’. Whether in history, philosophy or conversation, Emerson stresses the expansions or transitions of thinking the individual undergoes. Each of his major essays offers a series of such transitions.

3 Early works

Emerson’s philosophy is often taken as starting with his first book *Nature* (1836), where he expresses a sense of ‘decorum and sanctity in the woods’ and of vast ‘prospects’ for a culture of new thought and ‘new men’. The new culture can be achieved, and the beauty of the world restored, ‘by the redemption of the soul’, but this redemption takes place, Emerson emphasizes, according to no formula or model, but through ‘untaught sallies of the spirit, by a continual self-recovery, and by entire humility’.

Emerson’s distinctive philosophical voice emerges in ‘The American Scholar’ (1837) where, in one of the reversals characteristic of his thinking, he writes of the scholar less as a man in a library than as a complete ‘Man Thinking’, whose ‘dictionary’ is a life of free action. Influenced by but not ‘warped out of his own orbit’ by past writing, the scholar is an original source rather than ‘the parrot of other men’s thinking’. Emerson calls us back to ordinary life: to ‘the literature of the poor, the feelings of the child, the philosophy of the street, the meaning of household life’. Although he is often termed a ‘transcendentalist’, Emerson does not wish to transcend the common world. ‘I embrace the common, I explore and sit at the feet of the familiar, the low. Give me insight into today and you may have the antique and future worlds.’

‘An Address Delivered Before the Senior Class in Divinity College, Cambridge’, commonly known as the ‘Divinity School Address’ (1838), contains a fierce attack on institutional religion, but a defence of such ‘holy bards’ as Moses and Jesus. The ‘eastern monarchy of a Christianity’ thatEmerson finds around him treats the revelation as something that happened ‘long ago… as if God were dead’. But, Emerson insists, ‘God is; not was’.

Emerson’s first series of twelve essays contains some of his best-known work, including ‘History’, ‘Self-Reliance’, ‘The Over-Soul’ and ‘Circles’, as well as ‘Friendship’, ‘Spiritual Laws’, ‘Intellect’ and ‘Compensation’. Emerson thinks of history, like scholarship, primarily as a matter of the personal and the present, as ‘the desire to do away this wild, savage and preposterous There or Then, and introduce in its place the Here and the Now’. ‘The Over-Soul’ teaches a religion of the here and now to go along withEmerson’s present-oriented history and scholarship: ‘The simplest person, who in his integrity worships God, becomes God.’ ‘Circles’ expresses Emerson’s vision of flux and incompletion, in which ‘permanence is but a word of degrees’. Especially in morality, ‘there is no virtue which is final; all are initial’. Yet Emerson presents his own set of initial or experimental virtues, including especially ‘abandonment’ and ‘enthusiasm’.

‘Self-Reliance’ offers an indictment of the crowd or public - a ‘mob’ of ‘timorous, desponding whimperers’ - and a radical defence of the individual. ‘Whoso would be a man’, Emerson states, ‘must be a nonconformist’; and the healthy attitude of human nature is displayed in ‘the nonchalance of boys who are sure of a dinner’. Anticipating Nietzsche’s idea of the human creation of higher values, Emerson brazenly asks ‘What have I to do with the

sacredness of traditions if I live wholly from within?'

4 Mature philosophy

Emerson's 'Experience' dominates the second series of essays (1844), building an interpretation of human experience around the writer's grief at the death of his five-year-old son. The essay opens with the depiction of a series of stairs whose top and bottom we cannot see. This, Emerson tells us, is 'where we find ourselves'. Like many Emersonian essays, 'Experience' tells the story of 'the fall of man' and of rebirth or renewal - not through a foreign power but through contemporary 'men and women'. How can we make our way through 'the system of illusions' or the 'train of moods' in which we find ourselves, when there is no final, best view, no 'anchorage'? A newly pragmatic Emerson maintains that we can learn to skate over the surfaces of life; or, in a related metaphor, to find that 'everything good is on the highway'. The second series also includes 'Manners', where Emerson develops a philosophy of social relations that, anticipating Nietzsche, stresses the distance between individuals. In 'Nominalist and Realist' the final essay in the series, he develops a perspectival metaphysics that complements his epistemology of moods.

Emerson's preoccupation with the heroic develops most fully in Representative Men (1850), which includes essays on Plato, Napoleon, Montaigne,Shakespeare, Swedenborg and Goethe. The sceptic in the Montaigne essay takes a position between those of 'the abstractionist and the materialist', each of whom treats the world as more solid than it is. We are in fact 'spinning like bubbles in a river… bottomed and capped and wrapped in delusions'. Montaigne, the wise sceptic, develops a philosophy of 'fluxions and mobility… a ship in these billows we inhabit… tight, and fit to the form of man'.

The greatest of Emerson's late essays, 'Fate' (1860), dwells on the biological, physical and psychological forces controlling our experience. Our individual fortunes are fated, Emerson holds, in that the events that 'seem to meet' us are as much 'exuded' from our character as encountered. Yet he insists that there is also liberty or freedom, and that this liberty rests on our powers of thinking: 'if there be irresistible dictation, this dictation understands itself'. As in all his work, from *Nature* onward, Emerson records both our subjection to necessity and our powers of overcoming it. The ideal life, he suggests, can be achieved through a controlled oscillation or balance between 'Nature' and 'Thought'.

Emotion in response to art

The main philosophical questions concerning emotion in response to art are as follows. (1) What kind or type of emotions are had in response to works of art? (2) How can we intelligibly have emotions for fictional persons or situations, given that we do not believe in their existence? (This is known as 'the paradox of fiction'.) (3) Why do abstract works of art, especially musical ones, generate emotions in audiences, and what do audiences then have these emotions towards*? (4) How can we make sense of the interest appreciators have in experiencing empathetically art that is expressive of* negative *emotions? (A particular form of this query is 'the paradox of tragedy'.) (5) Is there a special* aesthetic *emotion, raised only in the context of experience of art? (6) Is there an irresolvable tension between an emotional response to art and the demands of aesthetic appreciation? Answers to these questions depend to some extent on the conception of emotion adopted.*

1 Introduction

Having emotions for art works or responding emotionally to them is a familiar enough occurrence, and hardly seems puzzling when recalled at that level of generality. Why should not works of art, in company with people, animals, natural objects and political events, produce emotions in us? Philosophers have, however, raised questions about emotional responses to art in particular contexts, where, viewed from certain angles, there is indeed something puzzling about them.

One such context is that of response to fictions (whether literary, dramatic or cinematic ones), where emotions appear to be had, not only for the work or representation itself, but for the fictional characters or situations represented therein, even though these are perfectly well understood not to exist. A second such context is that of abstract, or nonrepresentational art (music being the example *par excellence*), where it is unclear both what could elicit such a response and what its object could be. A third context is that in which art works expressive of negative emotion (for example, tragedies, requiems and tales of horror) engender parallel responses in perceivers without thereby being avoided or disapproved of by them. And a fourth context in which emotional response to art has struck philosophers as problematic is where the proper appreciation of art is at issue, when it is asked whether such appreciation is compatible with undergoing emotions of the familiar sort that art seems capable of raising in us.

2 The nature of emotions

In order to assess fruitfully the varieties of emotional response to art it is obviously of use to have some account of exactly what emotions are - in the occurrent, as opposed to the dispositional, sense. Philosophical debate on the nature of emotions, informed to greater or lesser degree by available work in psychology, has in the past thirty years or so revolved around an opposition between feeling-based (or sensation-based) approaches and thought-based (or cognition-based) approaches. The former holds that at the core of an emotion is an internal feeling or set of sensations, while the latter holds that at its core an emotion is a particular kind of thought, judgment or evaluation. While the feeling approach has trouble with the intentionality (or object-directedness) and amenability to reason of many emotions, the thought approach has trouble with the experiential aspect of emotions (that is, with what it is to feel them, as opposed to merely having the beliefs or entertaining the thoughts that may be associated with them), with the evident inertia and passivity of many emotional conditions, and with states of desire, whose connection with many emotions seems more than contingent. Still, while the feeling approach can be faulted for too 'mindless' a picture of emotions, it is right to insist on bodily response and inner affect of some sort as a *sine qua non* of emotion, and while the thought approach can be faulted for too 'mindful' a picture of emotions, it is right to emphasize that many emotions include cognitive elements essentially: for example, thoughts with specific contents, which contents are in many cases socially shaped.

At present there appears to be some consensus that, in perhaps the majority of cases, an emotion is best thought of as a bodily response with a distinctive physiological, phenomenological and expressive profile, one that serves to focus attention in a given direction, and which involves cognition to varying degrees and at various levels. The level of cognitive involvement runs from mere registering of presence, to ways of seeing or regarding that which is registered, to propositional conceptions of the object responded to, to articulate beliefs about or attitudes toward the object of response. Alternatively put, an experienced emotion can be said to have as its core a bodily reaction - comprising physiological sensations, feelings of comfort and discomfort, and orientings of attention - which

reaction is often caused or modified by, and is sometimes necessarily bound up with, cognitions of various sorts and strengths, depending on the type of emotion involved. Note that on such a view of emotion, in which cognitive representations on the order of beliefs (or for that matter, desires) are seen as characteristic of, but not essential to, experienced emotion, the intentionality or directedness of emotions (as opposed, say, to moods) is preserved by the root feature of orientation of attention to or focusing of concern on that which the subject registers as significant.

On the other hand, there is also a growing acknowledgment that the pre-theoretically recognized emotions constitute an irreducibly heterogeneous class, that is, that they do not form a 'natural kind'. It seems reasonable to recognize a spectrum of emotional states experienced by humans, from the startle reaction, involving minimal cognition, at one end, to pride, envy, shame, jealousy, grief, remorse, embarrassment and the like, involving complex and often morally conditioned cognitions, at the other end, with hunger, surprise, lust, fear, anger, joy, sorrow and so on filling the vast middle ground. The emotional responses typical of engagement with art, though, tend to be of a sort that has a moderate or high cognitive involvement - a fact relevant to some recent attempts to dissolve too quickly the paradox of fiction by appeal to what need not be true of all cases of emotion.

Although it is convenient to speak of emotions having elements or components of various sorts (for example, thoughts, sensations, desires, feelings, pleasures, pains, shifts of attention), these should not be thought of as merely bundled together, and the emotion as a mere conglomeration. The truth is rather that an emotion is an *ordered* complex or structure of the elements it is taken to comprehend, with *causal* relations prominent among those in which this order consists. My anger at my daughter for having carelessly misplaced my keys, for example, is a bodily response, rooted in physiology and reflected in countenance, involving a focusing of attention on her, and feelings of agitation and displeasure, which result jointly from my thought of her action and my desire that she should not have so acted, while fuelling, perhaps, my desire that she in some way pay for having so acted.

3 Emotional response to representational art: the paradox of fiction

The much-discussed paradox of fiction can be formulated as a set of three propositions, to each of which we seem to have strong allegiance, but which are jointly inconsistent, and thus impossible to maintain coherently as a set. Solutions to the paradox, then, typically take the form of a rejection of one or more of the propositions, with a reasoned justification for doing so. The propositions are these:

(a) We often have emotions for fictional characters and situations known to be purely fictional;
(b) Emotions for objects logically presuppose beliefs in the existence and features of the objects in question;
(c) We do not harbour beliefs in the existence and features of objects known to be fictional. In the extensive discussion in the literature of this conundrum, almost every possible solution to it has been aired. The following comprise most of the solutions that have found adherents.

(1) The Non-Intentionalist solution: emotional responses to fictions are not, despite appearances, instances of emotions as such, but rather of less complex states, such as moods (cheerfulness, for example) or reflex reactions (shock, for example), which lack the full intentionality and cognitivity of emotions *per se*. As is evident, this solution involves the denial of (a). But the diagnosis it offers seems to apply comfortably to only a small portion of the full range of sustained responses to fictions.

(2) The Suspension-of-Disbelief solution: while caught up in fictions, consumers thereof temporarily allow themselves to believe in the nonexistent characters and situations of the fiction, and thus to have bona fide emotions for them, reverting to standing beliefs in their nonexistence once the fiction no longer actively engages them. Such a solution, turning on a denial of (c), though popular in the nineteenth century, unacceptably depicts consumers of fiction as having both a rather tenuous grip on reality and an amazing ability to manipulate their beliefs at will.

(3) The Surrogate-Object solution: emotional responses to fictions take as their real objects not known-to-be-nonexistent persons and events in fictions, but other existent and believed-to-be-existent objects. This solution, in one way or another, thus calls (a) into question.

On one version of this solution, the object of response is simply the fictional work or artistic representation itself, or parts thereof. On another version, the objects of response are rather the descriptions, images, propositions or thought contents afforded *by* the fiction or representation. And on a third version, different enough from the

preceding two to deserve a separate label - the Shadow-Object proposal - the objects of response are real individuals or phenomena from the subject's life experience, ones resembling the persons or events of the fiction, of which the fiction puts the subject covertly or indirectly in mind.

The Surrogate-Object solution in its first two guises distorts the logic and phenomenology of emotional response to fictions. Whatever the nature or status of our response to fictional characters or situations, it is an emotional response to *them*, not to something else. Our responses, however ultimately analysed, have those characters and situations as their evident objects, and not the vehicles that bring them to us or the thoughts through which they are delineated. Much the same complaint can be brought against the Shadow-Object proposal, though here it is clear that the sort of response to which the proposal draws attention does indeed often accompany and underlie the emotional response to fictional matters *per se*. Still, despising a fictional character, say, is not simply reducible to despising people of that sort generally, or to despising some actual similar individual of one's acquaintance.

(4) The Anti-Judgmentalist solution: emotional responses to objects do not logically require beliefs concerning the existence or features of such objects, but only weaker sorts of cognitions, for example, seeing a certain way, conceiving in a certain manner or regarding as if such and such; thus, there is no good reason not to categorize the emotional responses had towards fictions as standard emotions, since they satisfy the demands of a more relaxed cognitivism about emotions. This approach to the paradox, which directly challenges (b), has a growing number of proponents, and merits extended discussion.

The instances of emotional response that challenge judgmentalism - the view that the cognitive element involved in all emotions is a judgment or belief - are mostly of two types. The first type is where there is insufficient time for cognition as such, so that no real representation of the object responded to is formed, there being only a virtually instantaneous reaction, instinctive or reflexive in nature, unmediated by conscious thought (examples: apprehension at a suddenly looming shape, disgust at an accidentally felt slug). A second type is where, though cognition is involved in generating the response, the representation thus formed is either not propositional in nature, or else does not have the status of a judgment, or both (examples: phobic fear of garter snakes, unfounded resentment of female superiors).

As noted earlier, the emotions involved in responding to fictions (for instance, pity, sorrow, love, admiration, anger, hate, hope) lie in the main in the middle and upper ranges of cognitive complexity for emotions. It thus seems undeniable that, whether or not they involve beliefs, such emotions are centrally mediated by representations of various sorts, such as views, conceptions or evaluations, which serve to *characterize* the object of response.

However, even if emotions at this cognitive level do not necessarily involve beliefs of a *characterizing* sort about their objects, such emotions, it seems, must still involve *existential* beliefs in regard to those objects, or something very close to that; that is to say, attitudes or stances of the order of 'taking to exist' or 'regarding as existent'. Otherwise, the state attributed becomes unintelligible, whether as an emotion or anything else. How can one be said to pity, fear, admire or hate something that one does not, concurrently with one's emotion, at least take or regard as existing, now or at some other time? If indeed that cannot be said, then the problem resurfaces, despite what is right in the critique of judgmentalism: since sane consumers of fiction do not regard fictional characters as existing, even when fully engaged with them appreciatively, they cannot really be in the full-fledged emotional states they are casually said to inhabit. The paradox of fiction is proof against anti-judgmentalist dissolution, even if we grant that emotions can occur without characterizing beliefs.

The sticking-point of the paradox is the dimension of existence and nonexistence, as this connects to the cognitive characterization that emotions of the sort in question minimally require. When we view or conceive an object as having such and such properties, whether or not we strictly believe that it does, we must, on pain of incoherence, be taking it to exist or regarding it as existent. For nothing can coherently be viewed or conceived as having properties without at the same time being treated as existent. A case of genuine emotion of a cognitively mediated sort, unlike a corresponding emotional response to a fictional character, involves at least viewing or conceiving an object as having such and such features, which thus in turn presupposes regarding it as existent or taking it to exist.

But I do not, when reading Dostoyevsky's *The Brothers Karamazov*, take Smerdyakov to exist, and so cannot

strictly be viewing or conceiving him as having properties, such as being base or being a murderer. And though my evaluative Smerdyakov-thoughts, generated as I read, may largely be what causes my hate response, directed ostensibly at him, for that response to strictly have *him* as its object, and so count clearly as an instance of hatred *of* Smerdyakov, requires, once more, that I take him to exist - which I clearly do not. It may, however, be the case both that I imagine or make-believe that someone to that effect exists, and that as a result I imaginarily, or make-believedly, experience for him an emotion of hate.

(5) The Surrogate-Belief solution: certain emotional responses to fictions (for instance, that of pity) require only beliefs that, *in the fiction*, the character exists and is or does such and such, and those beliefs are indeed widely held by rational consumers of fiction. This solution thus rejects (c), though not in the manner of Suspension-of-Disbelief theorists.

However, the beliefs this proposed solution highlights, beliefs about what is fictionally the case, can only ground the truth of one's fictionally or imaginarily pitying a character, not of one's literally doing so. Furthermore, that such beliefs play a role in generating emotional responses to fictions does not touch the heart of the paradox, which is that intelligible emotions for objects of the sort typical of engagement with fiction conceptually require beliefs in the existence of such objects, or at a minimum, an existential stance towards them. Beliefs about how things are fictionally can *cause* emotional reactions of some sort, to be sure, but they cannot logically ground intelligible emotions for entities whose existence is denied. Even where the emotion in question is such as to constitutively require beliefs, they are the wrong sort of beliefs partly to constitute such emotions. The beliefs I have 'about' Anna Karenina, say, cannot coherently make her the proper object of any pitiful reaction I might have. Pity involves concern for the welfare of some creature and distress at its suffering. If one does not believe such welfare or suffering is actual, what can one be concerned *for* or distressed *about*? Pity may likewise involve wishes or desires with respect to the thing pitied, but in the absence of a belief in the thing, or more loosely, an existential commitment to it, there cannot coherently be any such wishes or desires.

(6) The Irrationalist solution: while caught up in fictions, consumers of fiction become irrational, responding emotionally to objects that they know do not exist and thus do not have the features they are represented as having. Irrationalists either implicitly deny (c), proposing that we do in some manner endorse the existence of fictional characters and events - while apparently at the same time disavowing them - which qualifies as irrational, in the sense of being inconsistent, or else they implicitly deny (b), holding that we can have emotions for such as fictional characters and events, towards which we lack the usual beliefs, but qualifying such emotions consequently as irrational, in the sense of being unwarranted.

On the first construal the Irrationalist solution closely approaches that of Suspension-of-Disbelief, with the difference, perhaps, that no attempt is made to mitigate the clash of existential stances involved by suggesting that they are not simultaneously in full force. On the second construal the Irrationalist solution holds appreciators of fiction at fault, not for believing what they already believe the negation of - that fictional characters and events exist - but for emotionally responding to such characters and events in ways contraindicated by their beliefs.

It might seem that the Irrationalist solution, on this second construal, is saved from being a non-starter by the rejection of judgmentalism, since otherwise it could be held to be simply impossible, rather than just possibly irrational, to experience full-fledged emotions in the absence of certain beliefs. But as suggested earlier, if the critique of judgmentalism, applied to emotions of the sort that fiction typically elicits, shows only that characterizing beliefs, as opposed to existential ones, may be absent in such cases, the logical space this construal hopes to occupy may not be available. In any event, in the judgment of most commentators, portraying the normal consumer of fiction as fundamentally enmeshed in irrationality, however this be understood, is too high a price to pay for this to be an acceptable solution to the paradox.

(7) The Make-Believe, or Imaginary, solution: emotional responses to fictions cannot, despite appearances, be instances of the ordinary emotions with whose names we tend to label them, but are instead instances of imaginary or make-believe emotions. For, first, the standard emotions of life arguably have belief or belief-like presuppositions, notably existential ones, that are not fulfilled in normal engagement with fictions; and second, such emotions have motivational or behavioural consequences that are not in evidence in the course of such engagement.

The proposal is that in our interactions with works of fiction we experience make-believe emotions, or make-believedly experience emotions, for fictional characters and situations; it is thus (a) that is rejected on this solution. Make-believedly experiencing fear, say, is sufficiently similar to really experiencing fear, especially internally, that it is easily confused with it, and yet make-believedly experiencing fear can be reconciled (while really experiencing fear cannot) with the absence of existential endorsement and motivational upshot *vis-à-vis* the fictions that are feared. In this way the paradox is finally resolved.

In considering this solution, it is important to distinguish the claim that what we feel for fictional characters is *some* kind of emotion, or constitutes emotional response in the *broad* sense, from the claim, here disputed, that what we feel for fictional characters and describe with some ordinary emotion-word is literally an example of such emotion. We are indeed moved, this solution affirms, but not strictly to the standard emotions whose names come to our lips. Note also that to qualify our emotions for fictions as imaginary is to say that they are ones we imagine ourselves to be having, on the basis of experiences contributory to emotion that we are *actually* having, but does not imply that such emotions are illusory or unreal.

Though the Make-Believe proposal probably provides the best resolution to the paradox of fiction as such, a full account of our emotional responses when engaged with fictions - as opposed to our emotions for fictional characters *per se* - will want to acknowledge what is called to our attention by the Non-Intentionalist and Surrogate-Object proposals as well. And even the Irrationalist proposal, on the first construal, may contain a grain of truth; for perhaps we are, at least at moments of maximum involvement, in the incoherent states of mind it postulates as ours throughout.

4 Emotional response to abstract art: music and feeling

Emotional response to abstract art is puzzling, principally because the strategies that provide obvious explanations of both why we respond emotionally, and what we are responding to, in the case of representational art, seem not to be available. A novel, film or Impressionist landscape gives me the image of a human world, elements of which I can empathize or identify with, react to sympathetically or antipathetically, or even mirror unthinkingly, by a sort of natural contagion. But with a symphony, sonata, minimalist sculpture or Abstract Expressionist painting such explanations appear to have no purchase. Human beings and their predicaments are notably absent, at least as far as representation is concerned. So why or how does perception of such art works raise emotion, and on what is such emotion directed? Concentrating for brevity's sake on the art of music, rough answers are as follows.

In so far as music is capable of eliciting emotions in listeners, this appears to work through two different routes or mechanisms, typically operating in tandem. The first we may label the sensory or cognitively unmediated route, and the second the perceptual-imaginative, or cognitively mediated route. It seems undeniable that music has a certain power to induce sensations, feelings and even moods in virtue of its basic musical properties, virtually without any interpretation or construal on the listener's part. Particular timbres, rhythms, intervals, dynamics and tempi exemplify this power most clearly. Such properties need only be registered, as it were, to have their effect, at least for one acclimatized to a given musical culture. The rise in heartbeat caused by rapid tempo, the discomfort occasioned by dissonant intervals, the kinetic impulses induced by dancing rhythms, the excitement produced by quick alternations of soft and loud, the relaxation engendered by a certain tone colour or manner of articulation, are all familiar phenomena. But if the capacity of music to elicit emotion were exhausted by the direct effects of sensing basic musical features, it would be a poor thing, falling far short of the evocation of emotions proper, or even the semblance of such. The gap is filled by the second, or cognitively mediated, route to such evocation.

In addition to presenting an array of sonic features, simultaneously and successively, much music offers the appearance of human emotion, or of persons outwardly manifesting emotional states; arguably, that is what the expressiveness of music largely consists in (see Expression, artistic). In other words, music is often heard as, or heard as if, or just imagined to be, the expression of emotion by an unspecified individual, whom we may call the music's 'persona'. The degree of resemblance between the shape of music and the behaviour through which emotions are commonly expressed in life will have something, though not everything, to do with our being disposed to hear music in such ways. In any event, once this occurs, the mechanisms mentioned above and familiar from appreciation of representational art - mirroring, identification, empathy, sympathy, antipathy - can come into play, resulting in the arousal in the auditor of those same emotions, or else the feelings characteristic of them, or else those emotions on an imaginary plane. The sensory aspect of music alone indeed seems capable of inducing in

us at least a number of simple states of arousal ingredient in many emotions. But it is the perceptual-imaginative aspect, manifested in our disposition to hear emotion or emotional expression in music, that is surely primarily responsible for the complex, more robustly emotional responses to music, whether mirroring or reactive, that so many listeners report.

It remains to add that these mechanisms do not operate in total isolation from each other. The emotion which I hear a passage as expressing may soften or accentuate the particular psychological effect some basic musical feature produces on me, while the effect induced in me largely unthinkingly by some basic musical feature may influence and constrain the emotion of which I am disposed to hear an image in the music.

But if emotions are often produced in listeners in virtue of listening to emotionally expressive music, towards what are such emotions directed? Music neither supplies any objects, nor appears itself to be an appropriate object, for at least the vast majority of such emotions as are putatively aroused. In addition, music does not seem to provide anything that would justify the beliefs or attitudes towards objects that many objects can be held to require. Among the ways of responding to this difficulty are the following.

It can be held that music produces only moods in listeners, moods which intrinsically lack intentionality (anxiety or elation, for example), or else that it produces ‘objectless’ emotions, ones characteristically taking objects but somehow lacking them when aroused by music, for example, sadness or joy directed on nothing, or on nothing in particular.

Alternatively, it can be held that music produces in listeners just the *feeling* component of an emotion, together with the sense of focus or directedness inherent in the bodily response at the emotion’s core, but not the cognitions which characteristically accompany or even partly constitute the emotion.

Finally, it could be maintained that what music occasions in many listeners are states of *imaginary* emotion. The idea is that listeners readily erect, upon a basis of feelings produced in them by music whose expressiveness they empathetically grasp, imagined emotions of a corresponding sort, and that they do this through imagining, usually tacitly, objects and thoughts suitable to the emotions in question. The object of musical emotion, then, is not missing, but merely indefinitely posited in imagination, or is perhaps logically appropriated, as it were, from the emotion imaginarily ascribed to the music’s persona.

5 Emotional response to negatively emotional art: the paradox of tragedy

The paradox of negative emotion in art - of which the paradox of tragedy is a classical illustration - is this. Art that is negatively emotional, that is, art that represents, expresses or otherwise deals with emotions such as shame, grief, horror, sorrow, anger, remorse, despair and the like, seems to have a propensity to elicit parallel responses in appreciators. But if that is so, one would expect appreciators to avoid, or at any rate, judge as inferior, art of this nature. Yet not only do they not do so, but often they hold such art to be the highest or most rewarding of all.

A number of possible explanations have been given for how it is that persons rationally desire or value the empathic experience of negatively emotional art, given the ostensibly negative character of that experience. Here is a general categorization of such explanations.

(1) Compensatory explanations: negative emotion aroused by negatively emotional art is, as such, unpleasant, but undergoing it offers other rewards that compensate for this. (2) Conversionary explanations: negative emotion, which is initially or ordinarily a disagreeable response, is transformed, in the context of artistic appreciation, into something that is in fact agreeable, or at any rate, capable of being enjoyed. (3) Organicist explanations: negative emotion aroused by negatively emotional art is an essential element in a total experience, an organic whole, that is desired or valued. (4) Revisionary explanations: neither negative emotions, nor the feelings they include, are intrinsically unpleasant or undesirable, and thus there is nothing odd about appreciating art that induces such emotions or feelings. (5) Deflationary explanations: despite appearances, neither negative emotions, nor the feelings they include, are really aroused in us by negatively emotional art.

Compensatory explanations include Aristotle’s doctrine of catharsis, understood as a purging or purification of excess or unruly emotions of pity and fear through engagement with tragic drama, which justifies the raising of such emotions in the course of that engagement (see Katharsis). Another such explanation appeals to the value of knowledge of important truths of human existence that emotional engagement with negative art is said to afford. A

third explanation endorses such engagement, not for the knowledge of life it may afford, but rather for the knowledge of the art work it facilitates, emotional engagement with a work being seen as a necessary cost, in many cases, of fully understanding it. A fourth such explanation invokes the moral exercise that is provided, or the moral deepening that results, as a benefit of engagement with negatively emotional art. And a fifth explanation appeals to purely aesthetic pleasures in the beauty, lifelikeness or virtuosity of the representation or expression itself, positing these as enough to outweigh whatever negative emotion is undergone in their appreciation.

Conversionary explanations include Hume's explanation of the appreciation of tragedy; like that just noted, Hume's explanation highlights the pleasure in artistic representation and expression as such, but premises that this pleasure, being greater than the pain of the negative emotions concomitantly raised, does not simply offset that pain, but rather overwhelms and absorbs it, leaving an experience of uniformly positive character (see Hume, D. §3). A rather different conversionary explanation proposes that since the negative emotions raised by a work of art have no life implications for spectators, calling for no actions and betokening no real harms, such emotions must evidently be so altered by the artistic conditions under which they issue that, though still recognizable as this or that negative emotion (disagreeable affects intact), they are yet capable of being relished or enjoyed for experience's sake.

An example of an organicist explanation would be one invoking a satisfaction in the raising of some negative emotion by a work of art, perhaps because the emotion strikes one as appropriately raised in such circumstances, and oneself as admirably human for being thus susceptible. Such a satisfaction would obviously be inseparable from the negative emotion raised, in the fact of which satisfaction is taken. Another such explanation would appeal to the value of working through negative emotions in connection with a work of art, via immersion in its formal, narrative or dramatic structure, the emotions raised thus being an essential element in the experience valued as a whole.

Revisionary explanations are something like this: the experience of negative emotions is not intrinsically unpleasant; the affects involved (that is, sensations and feelings) are not in themselves disagreeable, and can be unproblematically savoured as such, in appropriate contexts. What is negative about negative emotions is only the *evaluation* of their objects that is central to such emotions. Thus, there is no special difficulty about people seeking these emotions from art.

Deflationary explanations come in at least three varieties. One of these hypothesizes artistic analogues of the life emotions, distinct from them in hedonic tone, conative connectedness and behavioural implication, and proposes that only these are raised in us by engagement with emotional art, and not the life emotions themselves. Another deflationary explanation simply flatly denies that anything like the ordinary emotions are evoked in subjects in the course of engaging with emotional art, and suggests that the subject's response, in so far as it is emotional, is exhausted by properly *appreciative* reactions, such as being moved by a work's beauty of expression. A third deflationary explanation maintains that spectators are always only make-believedly in states of negative emotion in virtue of engaging with a work of art, and that on the assumption that make-believe emotions of the negative sort are not inherently displeasing, there is no special problem about people tolerating or even actively pursuing such experiences.

Lack of space prevents a detailed assessment of these proposals, but there would seem to be more merit in compensatory and organicist explanations, and in the second of the conversionary explanations sketched above, than in revisionary or deflationary ones.

6 Emotion for art and aesthetic appreciation of art

Are there emotions unique to the appreciation of art, or aesthetic emotions *per se*, had when and only when a work is apprehended aesthetically? Past theorists, notably Clive Bell, have posited something of this sort, but such a posit has not lately found favour, nor does it appear to answer to any pressing theoretical problem about art. On the other hand, there may be an interesting category of positive emotions that, if not had uniquely for art, are both distinctive of the appreciation of art and not of the sort that typically figure in the content of art. Candidates would be admiration for a work's skill, fascination with a work's form, delight in a work's beauty, or awe at a work's depth of insight or expression. What might also figure here are experiences, remarked by many, of momentary will-lessness or self-transcendence occasioned by intense absorption in a work of art.

The question may also be raised as to the appropriateness of emotional responses to art of the ordinary sort. One form of this question concerns an apparent tension between the familiar picture of an emotion as a disturbing derangement of the psyche and the image of aesthetic appreciation as a state of calm and unclouded attention to a work of art.

The traditional notion of the aesthetic attitude, whose roots are in Kant, Schopenhauer and the eighteenth-century theorists of taste, depicts a frame of mind characterized by disinterestedness, detachment and disengagement from the practical (see Aesthetic attitude §3). But, charitably construed, such a notion demands only that one's personal situation or condition not be what primarily drives or directs one's response to a work, but instead, the humanly significant material that the work presents. In other words, such a notion need not call for suppression of emotional receptivity generally. So long as one's emotional response is a way of connecting to a work, of tracing its expressive outline or grasping its dramatic import, rather than a means of being distracted from it, or a springboard to wallowing in one's private concerns, then there is no conflict between responding to a work with a range of ordinary emotions on the basis of one's life experience and individual sensibility, and appreciating a work in an aesthetically appropriate manner as the specific embodiment of human content it is. By contrast, disinterestedness or detachment understood not as a principle for maintaining focus on a work rather than one's own circumstances, but as a desired end-state of impassivity or imperturbability, is nothing an account of artistic appreciation need embrace.

Emotive meaning

Emotive meaning contrasts with descriptive meaning. Terms have descriptive meaning if they do the job of stating facts: they have emotive meaning if they do the job of expressing the speaker's emotions or attitudes, or exciting emotions or attitudes in others. Emotivism, the theory that moral *terms have only or primarily emotive meaning, is an important position in twentieth-century ethics. The most important problem for the idea of emotive meaning is that emotive meaning may not really be a kind of meaning: the jobs of moral terms supposed to constitute emotive meaning may really be performed by speakers using moral terms, on only some of the occasions on which they use them.*

There are two components in emotivist accounts of the function and meaning of moral terms. One is a matter of relations to the speaker: moral assertions serve to express the speaker's emotions or attitudes. The other is a matter of relations to the audience: moral assertions serve to commend things, or to arouse emotions or attitudes in the audience.

The most celebrated accounts of emotive meaning were developed by A.J. Ayer and C.L. Stevenson. Ayer (1936) argued on general metaphysical and epistemological grounds that moral terms can only express and excite emotions. Stevenson (1937) developed a more detailed theory, relying more on distinctively ethical considerations (see Emotivism). These theories are liable to make moral discussion seem irrational, and to make no distinction between moral argument and propaganda. R.M. Hare developed a theory designed to remedy these defects. He argued that sentences using paradigm moral terms like 'good', 'right' and 'ought' are really disguised imperatives. Since there is a logic of imperatives, there is room for rational moral argumentation, and moral argument can be distinguished from propaganda, even though moral assertions do not primarily state facts (see Prescriptivism).

The most important difficulties for the idea of emotive meaning can be raised by asking whether the emotive meaning of moral terms is a matter of the speech act performed by someone using these terms, and, if so, what kind of speech act? One can distinguish between locutionary, illocutionary, and perlocutionary acts (or force). Locutionary acts are simply a matter of uttering certain words with certain senses and referents. Illocutionary acts are done *in* saying things; what illocutionary act one performs in uttering a sentence is determined together by the senses and referents of the words in the sentence and the context. Perlocutionary acts are done *by* saying things. That one performs a certain perlocutionary act is not guaranteed by performing an appropriate illocutionary act: it depends on further variable features of the context. Suppose Bob utters the words 'Down with the aristocrats!' before a large crowd in a revolutionary situation. Bob performs a locutionary act just by saying words with that meaning. In this context, Bob also performs the illocutionary act of *inciting* revolution. Bob's words may also, in that context, have the perlocutionary effect of *provoking* revolution; but this is not guaranteed by the locutionary or the illocutionary force of Bob's utterance. If Bob is sufficiently unpopular, his advocating revolution may actually dampen revolutionary enthusiasm. This classification suggests that the order of explanation typically goes from the locutionary to the illocutionary and the perlocutionary: it is in virtue of the sense and reference of the words one utters and the context that one performs a certain illocutionary act, and that one performs certain perlocutionary acts. The presumption is that an account of meaning will begin with sense and reference; if it begins with illocutionary or perlocutionary acts, it may begin in the wrong place (see Speech acts).

Some early accounts of emotive meaning seem to identify the meaning of moral assertions with perlocutionary acts (for example, arousing emotions). But this seems both to be the wrong place to begin and to raise a further concern. If we think of meaning as a matter of convention, not (mere) causal variation, then causal correlations between utterances and the production of certain effects are not really meanings. Perhaps then emotive meaning is a matter of illocutionary force. Unfortunately, seeing emotive meaning as illocutionary force is also problematic; in addition to the general problem that an account of meaning apparently should not begin with the illocutionary, there is the specific problem that moral terms do not seem *always* to have the right kinds of illocutionary force. Consider the suggestion that 'good' is used to commend. While it may be true that the term 'good' as used in 'This is a good tennis racket', uttered in a sports shop has the illocutionary force of commending a tennis racket, 'good' as used in 'If you can't get a good one there, try the shop down the street', does not obviously seem to commend anything.

Moral arguments raise especially acutely a version of the same problem for the view that emotive meaning is illocutionary force. Consider the argument: 'Telling the truth is good; if telling the truth is good, getting your little brother to tell the truth is good; so getting your little brother to tell the truth is good.' This argument looks valid. But while 'telling the truth is good' in its occurrence as the first premise commends telling the truth, in its occurrence in the second premise it does not seem to commend anything. So, the suggestion is, emotivists cannot account for the validity of some moral arguments, because if meaning is understood as illocutionary force, it is not the same between different occurences of the same words in arguments. This problem is often called 'the problem of unasserted contexts' (in the second premise, 'telling the truth is good' occurs unasserted).

Fans of emotive meaning can respond to these criticisms. Hare (1952), Blackburn (1984) and Gibbard (1990) have all offered solutions to the problem of unasserted contexts. It is certainly true that the meanings of *some* words (like 'promise') seem well explained by explaining the illocutionary act one performs in using them. Moreover, it is not an accident that, for instance, 'good' is often used to commend, while it is an accident if 'fast' is used to commend. Still, an attractive alternative to the theory that 'good' has emotive meaning is that 'good' *means* something like 'meets the relevant standards'. It is by virtue of this meaning that 'good' is often used to commend. Emotive force is then explained by meaning, not vice versa.

Emotivism

Emotivists held that moral judgments express and arouse emotions, not beliefs. Saying that an act is right or wrong was thus supposed to be rather like saying 'Boo!' or 'Hooray!' Emotivism explained well the apparent necessary connection between moral judgment and motivation. If people judge it wrong to lie, and their judgment expresses their hostility, then it comes as no surprise that we can infer that they are disinclined to lie. Emotivism did a bad job of explaining the important role of rational argument in moral practice, however. Indeed, since it entailed that moral judgments elude assessment in terms of truth and falsehood, it suggested that rational argument about morals might be at best inappropriate, and at worst impossible.

In the early part of the twentieth century, under the influence of logical positivism, a new view about the nature of morality emerged: emotivism (see Logical positivism). Emotivists held that when people say, 'It is wrong to tell lies', they express their hostility towards lying and try to get others to share that hostility with them. Moral claims were thus supposed to be very different from claims expressing beliefs. Beliefs purport to represent the world, and so are assessable in terms of truth and falsehood. Emotions, by contrast, do not purport to represent the world, so moral claims were supposed to elude such assessment (see Analytic ethics §1; Moral judgment §1). Judging acts right and wrong was thus rather like saying 'Boo!' and 'Hooray!'

Emotivism had evident appeal. It is widely agreed that there is a necessary connection of sorts between moral judgment and motivation. If someone judges telling lies to be wrong then they are motivated, to some extent, not to lie. But what people are motivated to do depends on what they approve of, or are hostile towards, not simply on what they believe (see Moral motivation). Imagine, then, that someone's judgment that telling lies is wrong expressed a belief. In order to know whether they are inclined to lie or not we would then need to know, in addition, whether they approve of, or are hostile towards, telling lies. But we need to know no such thing. Knowing that they judge lying wrong suffices to know that they are disinclined to lie. This fits well with the idea that the judgment itself simply expresses hostility.

Emotivism also had its difficulties, however. Though emotivists admitted that rational argument about morals had an important role to play, their view entailed that this role was strictly limited. Since they agreed that less fundamental moral claims are entailed by more fundamental claims along with factual premises, and since they agreed that factual premises could be criticized rationally, they held that less fundamental moral claims must be rationally-based. Someone who judges lying wrong because they think that lies are harmful must, they thought, change their mind on pain of irrationality if shown that lying is harmless. But at the same time they insisted that fundamental moral claims - those that are not so derived like, perhaps, the claim that it is wrong to cause harm - are immune from such rational criticism. This was the so-called 'fact/value gap' (see Fact/value distinction; Logic of ethical discourse).

It is unclear whether emotivists were consistent in allowing even this limited role for rational argument, however.

1 If it is wrong to cause harm and lying causes harm then it is wrong to tell lies
2 It is wrong to cause harm
3 Lying causes harm
Therefore, it is wrong to tell lies

This argument is valid only if 'It is wrong to cause harm' in premises (1) and (2) means the same thing. If this phrase means different things then there is an equivocation and the argument is straightforwardly invalid. Emotivism entails that someone who asserts (2) expresses hostility towards causing harm. Yet whatever 'It is wrong to cause harm' means in (1), it most certainly does not serve to express such hostility. In (1) the phrase appears in the antecedent of a conditional. Someone who asserts (1) may thus even deny that it is wrong to cause harm. They need therefore have no hostility to express towards causing harm.

Philosophers sympathetic to emotivism have tried to rescue it from this objection. There is a real question whether emotivists themselves should ever have been interested in preserving an important role for rational argument about morals, however. If the function of moral judgment is simply to express emotions and arouse like emotions in others then it follows that rational argument is at best one way, and perhaps not a very good way, of achieving

these aims. We might be more effective if we distracted people from the facts and used rhetoric, humiliation and brainwashing instead. It is hard to see how emotivists could find fault with the idea that a practice in which the use of such technologies was widespread could still constitute a perfectly proper *moral* practice.

The best emotivists could say at this point was, ‘Boo for persuasion and brainwashing!’ Philosophers who thought this response failed to acknowledge the central and defining role played by rational argument in moral practice concluded that emotivism extracted too high a price for its explanation of the necessary connection between moral judgment and motivation. Subsequent theorists have focused on whether an alternative explanation of the necessary connection is available, one which also accommodates the idea that rational argument plays such a central and defining role. No consensus on this issue has emerged, however.

If nothing else, emotivism succeeded in making clear how difficult it is to explain the necessary connection between moral judgment and motivation, together with the idea that rational argument plays a central and defining role in moral practice, if the emotions that cause our actions are assumed to be beyond rational criticism. Much recent work about the nature of morality proceeds by calling this assumption into question.

Empedocles (*c.*495-*c.*435 BC)

Empedocles, born in the Sicilian city of Acragas (modern Agrigento), was a major Greek philosopher of the Presocratic period. Numerous fragments survive from his two major works, poems in epic verse known later in antiquity as On Nature and Purifications.

On Nature sets out a vision of reality as a theatre of ceaseless change, whose invariable pattern consists in the repetition of the two processes of harmonization into unity followed by dissolution into plurality. The force unifying the four elements from which all else is created - earth, air, fire and water - is called Love, and Strife is the force dissolving them once again into plurality. The cycle is most apparent in the rhythms of plant and animal life, but Empedocles' main objective is to tell the history of the universe itself as an exemplification of the pattern.

The basic structure of the world is the outcome of disruption of a total blending of the elements into main masses which eventually develop into the earth, the sea, the air and the fiery heaven. Life, however, emerged not from separation but by mixture of elements, and Empedocles elaborates an account of the evolution of living forms of increasing complexity and capacity for survival, culminating in the creation of species as they are at present. There followed a detailed treatment of a whole range of biological phenomena, from reproduction to the comparative morphology of the parts of animals and the physiology of sense perception and thinking.

The idea of a cycle involving the fracture and restoration of harmony bears a clear relation to the Pythagorean belief in the cycle of reincarnations which the guilty soul must undergo before it can recover heavenly bliss. Empedocles avows his allegiance to this belief, and identifies the primal sin requiring the punishment of reincarnation as an act of bloodshed committed through 'trust in raving strife'. Purifications accordingly attacked the practice of animal sacrifice, and proclaimed prohibition against killing animals to be a law of nature.

Empedocles' four elements survived as the basis of physics for 2,000 years. Aristotle was fascinated by On Nature; his biology probably owes a good deal to its comparative morphology. Empedocles' cosmic cycle attracted the interest of the early Stoics. Lucretius found in him the model of a philosophical poet. Philosophical attacks on animal sacrifice made later in antiquity appealed to him as an authority.

1 Life and work

The first lines of Empedocles' poem *Purifications* give a flavour of the man:

> Friends, who live in the great city of the yellow Acragas, up on the heights of the citadel, caring for good deeds, I give you greetings. An immortal god, mortal no more, I go about honoured by all, as is fitting, crowned with ribbons and fresh garlands.
>
> (fr. 115)

Men and women followed him in their thousands, Empedocles says, wanting prophecies or remedies for diseases. Not surprisingly there accumulated in antiquity a huge conglomeration of fact and fantasy about the life and death of such a figure, summarized by Diogenes Laertius (VIII 51-75). A cautious sifting yields the following picture.

Empedocles was born of aristocratic family, a little after Anaxagoras. He died aged sixty. He was active in the political life of Acragas as a fierce opponent of oligarchy and tyranny. He had a reputation as an orator: Aristotle even makes him the inventor of rhetoric. He is described as a physician, but despite his profound interest in human physiology, anecdotes of his miracle working and the supernatural powers he claimed his teaching would impart (fr. 111) both strongly suggest a practitioner of magic, an activity doubtless to be seen in the context of his Pythagorean religious beliefs.

Among various writings ascribed to him, the two most important were *On Nature* and *Purifications*, hexameter poems probably in three and two books respectively. *On Nature* was at the time of its composition very likely the longest work of philosophy ever written and Empedocles' fragments constitute the largest corpus of original extracts to survive of any Presocratic. Scholars disagree about which of the fragments belong to which of the two major works - the sources seldom supply specific information on this point. In the age of Victorian rationalism it was supposed that *On Nature* presented a sober materialist philosophy of nature, subsequently abandoned in

Purifications for the intoxications of mystery religion. Fragments were assigned to the two poems accordingly. The basis for this division of the material has long since collapsed, and more recent study (notably by Kahn 1960) has suggested that *On Nature* itself draws religious morals from a philosophy which was always conceived in religious terms. Indeed, it has been argued that the great majority of the fragments, including those on religious themes, belong to *On Nature*, *Purifications* being simply a collection of oracles and ritual prescriptions designed to satisfy the desire for healing and salvation Empedocles mentions in its opening verses.

2 Pythagoreanism

Empedocles praises Pythagoras as a man of surpassing knowledge and 'wise works', with powers of foresight extending to ten or twenty generations ahead (fr. 129). What prompted this extravagant admiration was evidently Pythagoras' analysis of the human condition: to atone for sin the soul is subject to a cycle of reincarnations into a variety of living forms (since all life is akin) until release is eventually achieved (see Pythagoras §2). On this view animal sacrifice counts as unwitting slaughter of one's kin. Empedocles dramatizes the implication in some gothic hexameters:

> Father lifts up a beloved son changed in form, and butchers him with a prayer, helpless fool…. Similarly son seizes father and children their mother, and tearing out the life they consume the flesh of those they love.
>
> (fr. 137)

Further verses spell out the penalty bloodshed incurs, invoking an 'oracle of Necessity' which condemns guilty spirits (*daimones*) to wander apart from the blessed for 30,000 years, in all manner of mortal forms. They conclude with a dramatic confession: 'Of these I too am now one, an exile from the gods and a wanderer, having put my trust in raving Strife' (fr. 115).

Fragment 115 is said by Plutarch to have formed part of the preface to Empedocles' philosophy. Is this a reference to *Purifications* (the usual supposition)? 'Philosophy' rather suggests *On Nature*; and Empedocles announces the *recovery* of his divinity at the start of *Purifications* (see §1). On the basis of comparison with the proem to Lucretius' *On the Nature of Things* Sedley (1989) argues persuasively that the entire sequence of fragments just summarized helped to launch *On Nature*. Whether this is right or not, Empedocles' Pythagoreanism is the best clue we have to his intentions in *On Nature*. The poem should be seen as an attempt to exhibit the cycle of incarnation as an instance of a general pattern of repetition governing all change: plurality is converted into unity by the power of Love and unity is then broken into plurality by Strife, until the process is reversed and conversion of plurality into unity begins once again. What *On Nature* works out in detail is the realization of this pattern in the rhythms of plant and animal life and the design and dissolution of the body, but above all in the history of the universe itself (see Pythagoreanism §3).

3 The cycle of change

The cycle of change is announced in fragment 17.1-2: 'A twofold tale I shall tell: at one time they grew to be one alone out of many, at another again they grew apart to be many out of one'. These lines deliberately echo and defiantly contradict the assertion of Parmenides (§3) that there is only *one* tale to tell, that of changeless and timeless being and unity (fr. 8.1-6). The language of growth is not accidental. Empedocles has already indicated that the subjects of the dual process are what he calls the 'roots': earth, air, fire and water. Subsequent philosophy would speak of these as 'elements', but Empedocles chooses a designation which captures the idea that they are not merely the basis of everything else, but themselves have a potentiality for development. He is emphatic in his agreement with the Parmenidean thesis that nothing comes into being from non-existence or perishes into it: mixture and separation of roots are what humans mistakenly call birth and death (frs 8-12).

After amplification of the twofold tale Empedocles continues: 'And these things never cease their continual interchange, now through love all coming together into one, now again each carried apart by strife's hatred' (fr. 17.6-8). Mixture and separation would not occur without the agency of forces bringing them about. Are Love and Strife physical or psychological forces? For us it is counterintuitive to envisage earth or fire as capable of psychological responses. But *On Nature* is permeated with expressions of the hatred the roots have for each other, of their desire for one another. Empedocles does not write as though he wants the reader to construe them metaphorically. On the other hand, the operation of Love in creating mixtures of the roots is often also described in

the language of craftsmanship: she welds (frs 34, 96) and rivets (fr. 87) and fires like a potter (fr. 73). Here Love seems to represent whatever physical force makes for the assimilation of things. However we are to conceive of Love and Strife, they are certainly treated as existing independently of the roots. But there is a difference between them: Love is ‘among’ the roots, Strife ’apart from’ them (fr. 17.19-20). The implication is presumably that Love works with the grain, Strife against it: roots have a natural tendency to join together, whether earth with earth or in mixture with air, fire and water, whereas their separation is unnatural (fr. 22). Aristotle, however, found Empedocles thoroughly confusing on this issue (*Generation and Corruption* II 6).

Fragment 17.9-13 sums up the two key features of change - its oscillating duality and its ceaseless repetition - in a surprisingly Heraclitean conclusion (compare Heraclitus §3):

> So insofar as they have learned to grow one from many, and again they grow many as the one grows apart, thus far do they come into being and have no stable life; but insofar as they never cease their continual interchange, thus far they exist always, changeless in the cycle.

The implication is that Parmenides looked for changeless existence in the wrong place: it is not to be found in being (not even the being of the roots), but in the regularity of the cycle of unending flux.

4 The biological paradigm

The initial presentation of the cycle of change in fragment 17 is entirely general and abstract in its formulations. The evidence for the structure and content of the following section of *On Nature* is inadequate, although newly discovered fragments may clarify the matter (see Martin and Primaveri 1997). However Empedocles seems to have taken the creation of plants and animals as a paradigm of the way mixture of roots generates a huge variety of other forms (fr. 21). He appealed to the analogy of a painter, using a few pigments with many potentialities:

> When they seize pigments of many colours in their hands, mixing in harmony more of some and less of others, they produce from them forms resembling all things, creating trees and men and women, beasts and birds and water-bred fish, and long-lived gods, too, highest in honour.
>
> (fr. 23)

If this is how art achieves its effects, why should we look for any other explanation of the way nature produces the originals copied by the painter?

It may be that the paradigm of animal creation, once established, was subsequently invoked in later sections of the poem. For example, the following lines from fragment 20 might well have been written to support the notion expressed in fragment 31 of the disintegration of the limbs of the cosmic sphere:

> This is well-known in the mass of mortal limbs: at one time, in the maturity of a vigorous life, all the limbs that are the body’s portion come into one through love; at another time again, torn asunder by evil strifes, they wander, each apart, on the shore of life. So it is too for shrubs and water-housed fish and mountain-laired beasts and wing-progressing gulls.

5 Cosmic history

Mention of the cosmic sphere brings us to Empedocles’ boldest application of the concept of a cycle of change: to the history of the universe. He conceived that just as harmonization by Love and decomposition by Strife constitute the common pattern for the biological development of plants and animals, there must be a similar story to tell about the universe as a whole. But here he supposed that the unity achieved at one pole of the cycle and the division at the other took more radical and absolute forms than in the biological realm. When - as he described first as usual - the influence of Love is at its strongest, all distinctions disappear as reality becomes a perfect divine sphere (frs 27-9). Strife for its part generates a vortex which not only breaks the sphere down into its constituent roots, but achieves their complete separation. It is under Strife’s domination that the world as we are familiar with it comes into being (A37, 42).

Empedocles’ account of this development was evidently extensive, and included full discussions of all the topics by now traditional in philosophical cosmogony: notably, the formation of the earth, the sea, and the heavenly bodies, and the evolution of life. Strife divides the roots into four great isolated masses. What happens next is

obscure, but the key process was physical interaction between these masses: some of its effects inevitable, some pure chance (see, for example, fr. 53). In particular, misty air heated by fire rises up and forms a nocturnal hemisphere balanced by a diurnal counterpart of fire. The sun is a reflection of this fire, the moon compacted air. The earth too sweats under the heat of the sun, which is the origin of the sea (A30, 49, 66).

The power of Strife is clearly not what it was, but we hear nothing yet of Love. Its influence begins to be apparent with the emergence of life. A clear example is the creation of bone, ascribed to *harmonia*, one of Empedocles' synonyms for Love: 'And kindly earth received in its broad melting-pots two parts of the gleam of Nestis [water] out of eight, and four of Hephaestus [fire], and they became white bones, marvellously joined by the gluing of harmonia' (fr. 23). The creatures to which bodily parts such as this belonged were described subsequently, in Empedocles' memorable theory of evolution:

> Empedocles held that the first generations of animals and plants were not complete, but consisted of separate limbs not joined together; the second, arising from the joining of these limbs, were like creatures in dreams; the third was the generation of whole-natured forms. The fourth arose no longer from the homogeneous substances such as earth or water, but by intermingling, in some cases as the result of the compacting of their food, in others because female beauty excited the sexual urge. And the various species of animal were distinguished by the quality of the mixture in them.
>
> (A72)

Surviving fragments give vivid details of the bizarre beings of the first three stages (frs 57-62). From these it is clear that in the first two especially chance was made responsible for a great deal. Empedocles may have talked in this context of the survival of the fittest: a remarkable anticipation of Darwinism, although criticized by Aristotle for its inability to account for the regular teleological patterns of nature (*Physics* II 8). It is only with the animals of the fourth (that is, present) stage that Love begins to exercise a control over the whole structure and pattern of life (fr. 71). The evidence suggests that at this point in the poem Empedocles included a full-scale comparative biology of plant and animal species, focused on explanation of the formation and function of the parts of the body.

Ultimately all this diversity would be reabsorbed into the divine sphere. *On Nature* may have concluded with some verses which foreshadow this, speaking of god as a mind, 'holy and beyond description, darting through the whole universe with swift thoughts' (fr. 134).

Aristotle sometimes talks as if he thinks two cosmogonies were envisaged: one occurring as Strife grew more powerful, another as its influence ebbed. He then complains that Empedocles said and could say nothing about the second (A42). Some modern commentators have reinforced this idea of a double cosmogony, adding a double zoogony and appealing to some obscure lines which speak of a 'double birth and double failing of mortal things' (fr. 17.3-5). But it seems likely that this is just a reference to the growth of unity, then of plurality, both 'mortal' conditions persisting only for a while. In any event, the reduplicating interpretation is hard to reconcile with the shape of the cosmic history as it emerges from the rest of the fragments.

Another way of reading Empedocles' history of the universe is as an arbitration and synthesis between two approaches to cosmogony adopted by different among his philosophical predecessors. Broadly speaking, the Ionians from Anaximander on explain the emergence of a world or worlds as the outcome of separation from an original undifferentiated condition, and of the consequent interaction between the physical forces released by the separation. By contrast, in the cosmological part of his poem Parmenides had posited an original duality of fire and night, and explained the development of cosmic order and life on earth as the work of Aphrodite mixing the two basic forms (Parmenides fr. 13). Empedocles implies that each strategy is half right: separation produces a differentiated universe, but mixture the biosphere.

There is in fact reason to think that Empedocles wanted to be read as among other things an encyclopedist of previous thought. For example, the forms generated in the early phases of evolution are not just the stuff of dreams, but also recapitulate and rationalize myth. Most notable of these is the figure of the Minotaur, surely the model of Empedocles' 'ox-headed man-natured' being (fr. 61). At the opposite extreme, his verses describing the divine sphere deliberately recall Xenophanes' god (see Xenophanes §3) - 'No twin branches spring from his back, no feet, no nimble knees, no fertile parts' (Empedocles, fr. 29) - and that of Parmenides' being - 'Thus he is held fast in the close obscurity of *harmonia*, a rounded sphere rejoicing in joyous solitude' (Empedocles, fr. 27).

6 Biological explanations

The power of Empedocles as a thinker and his gifts as a poet are most happily married in the surviving extracts of his biology, where he shows an extraordinary capacity to get the reader to *see* the kinship of all nature. Sometimes parts of animals with homologous functions are just listed: 'The same things are hair and leaves and close-packed wings of birds and scales, coming into being on sturdy limbs' (fr. 82). Sometimes metaphor makes the point: 'Thus do tall trees lay eggs: first olives… ' (fr. 79). Other animals are armed with horns or teeth or stings, but 'Sharp-speared hairs bristle on hedgehogs' backs' (fr. 83).

Perception was explained by an ingenious theory of pores and effluences. It occurs when pores in the sense organ are just the right size to admit effluences of shape, sound, etc. given off by things (A92). The theory was employed to account for other phenomena also, such as chemical mixture (frs 91-2, A87) and magnetism (A89). Only like things (or things made like by Love) could have symmetrical pores and effluences. Empedocles posits fire in the eye for perception of light colours, a resounding bell in the ear to account for hearing, and breath in the nose for smelling (A86). Little of this material survives in his own words, except for an extended simile:

> As when someone planning a journey through the wintry night prepares a light, a flame of blazing fire, kindling for whatever the weather a linen lantern, which scatters the breath of the winds when they blow, but the finer light leaps through outside and shines across the threshold with unyielding beams: so at that time did she [Aphrodite] give birth to the round eye, primeval fire confined within membranes and delicate garments, and these held back the deep water that flowed around, but they let through the finer fire to the outside.
>
> (fr. 84)

Empedocles made thinking a function of blood around the heart (fr. 105). Of all physical substances blood comes closest to an equal blending of all the elements, even though its origin still owes something to chance (fr. 98). This is what equips it to grasp the nature of things: earth with earth, and so on - but also Love with Love and Strife with Strife (fr. 109).

7 Sacrifice

Empedocles relates his guilt over bloodshed to 'trust in raving strife' (fr. 115). As all creation of plants and animals is due to the power of Love, so Strife is the invariable cause of their dissolution and death. It is in his account of blood that Empedocles describes the mixture of the roots as 'anchored in the perfect harbours of Kypris [Love]' (fr. 98). Hence to kill by spilling blood is to act against the principle that makes for all that flourishes and enjoys harmony. It is no surprise that Empedocles conceives it as madness.

Theophrastus tells us that in his account of 'sacrifices and theogony', usually taken to belong to *Purifications*, Empedocles portrayed a golden age when humans recognized only Love as a god: 'They did not count Ares a god nor Battle-cry, nor was Zeus their king nor Kronos nor Poseidon, but Kypris [that is, Aphrodite] was queen' (fr. 128). There was no animal sacrifice:

> Her they propitiated with holy images, with paintings of living creatures, with perfumes of varied fragrance and sacrifices of pure myrrh and sweet-scented frankincense, throwing to the ground libations of yellow honey. The altar was not drenched with the unspeakable slaughters of bulls, but this was held among humans the greatest defilement - to tear out the life from noble limbs and eat them.
>
> (fr.128, continued)

Empedocles envisages this golden age as a time when humans were in fact friends with the rest of animal creation: 'All things were tame and gentle to humans, both beasts and birds, and friendship burned bright' (fr. 130). Is the image of harmony painted in these passages intended as part of the cosmic history? According to Empedocles' theory of evolution Strife was more, not less, dominant in the past. We should infer that like most pictures of primal bliss, this too is designed to function principally as an ideal measure of contemporary misery and wickedness.

What Empedocles lays down for all time is a moral rule against killing living things, whose expression led Aristotle to treat it as a paradigm of how natural law is to be conceived: 'That which is the law for all extends unendingly throughout wide-ruling air and the boundless sunlight' (fr. 135). Particular Pythagorean injunctions

against touching beans and laurel leaves are recorded as Empedoclean (frs 140-1). As for the future, other verses promise the repentant sinner eventual release from the burden of reincarnation entailed by committing bloodshed:

> At the end they come among humans on earth as prophets, bards, doctors and princes; and thence they arise as gods highest in honours, sharing with the other immortals their hearth and table, without part in the sorrows of men, unwearied.
>
> (frs 146-7)

Empedocles no doubt found the killing of other humans as horrific as animal sacrifice - the lines in which he represents sacrifice *as* infanticide etc. trade on a particular form of revulsion on the part of the reader. But he directs his outrage at violence to life as such, and more specifically at the assumption that blood-shedding can form part of a proper form of worship. In other words, his protest aims both to broaden our moral horizons and to reform religion. It should be seen as a radical challenge to the entire cultural framework of the ancient Greek city-state.

Empiricism

In all its forms, empiricism stresses the fundamental role of experience. As a doctrine in epistemology it holds that all knowledge is ultimately based on experience. Likewise an empirical theory of meaning or of thought holds that the meaning of words or our concepts are derivative from experience. This entry is restricted to epistemological empiricism. It is difficult to give an illuminating analysis of 'experience'. Let us say that it includes any mode of consciousness in which something seems to be presented to the subject, as contrasted with the mental activity of thinking about things. Experience, so understood, has a variety of modes - sensory, aesthetic, moral, religious and so on - but empiricists usually concentrate on sense experience, the modes of consciousness that result from the stimulation of the five senses.

It is obvious that not all knowledge stems directly from experience. Hence empiricism always assumes a stratified form, in which the lowest level issues directly from experience, and higher levels are based on lower levels. It has most commonly been thought by empiricists that beliefs at the lowest level simply 'read off' what is presented in experience. If a tree is visually presented to me as green I simply 'register' this appearance in forming the belief that the tree is green. Most of our beliefs - general beliefs for example - do not have this status but, according to empiricism, are supported by other beliefs in ways that eventually trace back to experience. Thus the belief that maple trees are bare in winter is supported by particular perceptual beliefs to the effect that this maple tree is bare and it is winter.

Empiricism comes in many versions. A major difference concerns the base on which each rests. A public version takes beliefs about what we perceive in the physical environment to be directly supported by experience. A phenomenalist version supposes that only beliefs about one's own sensory experience are directly supported, taking perceptual beliefs about the environment to get their support from the former sort of beliefs. The main difficulties for a global empiricism (all knowledge is based on experience) come from types of knowledge it is difficult to construe in this way, such as mathematical knowledge.

1 Versions of epistemic empiricism

There are broad distinctions within epistemology that affect empiricism as well as other positions. One can think of *knowledge* or of *justified belief* as based on experience. To simplify the discussion we concentrate on the latter whenever we get into the details, though it is sometimes convenient to speak in terms of knowledge. If, as is often supposed, knowledge is justified belief that meets further conditions, then the necessity of an empirical basis for justified belief will extend to knowledge as well. There is also the question of whether the justification of belief depends on what the belief is *based on* (what gives rise to it), or whether it simply depends on what the believer *has* in the way of possible grounds, reasons or evidence, whether made use of or not. We take the former as a basis for discussion. Thus the empiricism under consideration here holds that all justified beliefs acquire their justification from being based, directly or indirectly, on experience.

Although empiricism typically concentrates on sense experience, this is not the only possibility. It is plausible to suppose that one's introspective knowledge of one's feelings, desires and other mental states derives from one's experience of those states (see Introspection, epistemology of). There is also a religious empiricism that takes certain beliefs about God to be justified by being based on a (frequently non-sensory) experiential presentation of God (see James, W. §4; Religious experience). This entry is restricted to sensory empiricism.

Empiricism comes in stronger and weaker forms. One such distinction has to do with scope - whether the view takes all knowledge to be based on experience, or restricts this claim to knowledge of the physical universe, excluding, for example, mathematical and/or religious knowledge. There are also differences regarding the strength of support lower levels must give higher levels in order that the beliefs at the higher levels be justified.

2 A phenomenalist empirical base

A common-sense form of empiricism takes perceptual beliefs about the physical environment (external beliefs) to be directly supported by experience - such beliefs as 'that house is on fire', 'a rabbit just ran across the yard' or 'a car is parked in front of the house'. But there are considerations that have driven philosophers to retreat to phenomenal beliefs about one's own sensory experience as constituting the base. For one thing, external beliefs are

often not solely based on experience, but rest, at least in part, on other beliefs. Thus I typically recognize a book as my copy of *Principia Ethica* not just by the way it looks (many other copies look just like that), but also by the fact that it is on a shelf in a study that belongs to me. For another thing, external beliefs can be mistaken even if confidently based on sense experience. I may unhesitatingly form the perceptual belief that the car in front of the house is a Pontiac when it is a Buick. Many philosophers have felt that if empirical knowledge is to be worthy of the name, at least the foundations on which it rests must consist of absolutely certain knowledge that cannot possibly be mistaken (Lewis 1946). Finally, it has been held that since, when I form an external perceptual belief, I would, if I reflected on the matter, take the justification of that belief to be the sensory experience on which it is based, that shows that beliefs about sensory experience are more basic in our empirical knowledge. All this can drive one to take phenomenal beliefs as the only ones that are directly supported by experience, with external beliefs supported by the phenomenal beliefs.

And yet these considerations do not require that conclusion. It remains to be shown that beliefs must be mistake-proof to constitute an empirical base. And the fact that external perceptual beliefs are based on sense experience should not be confused with the claim that they are based on beliefs about sense experience. Finally, even if my belief that this is my copy of *Principia Ethica* is partly based on other beliefs, that would prevent it from figuring in the empirical base only on an extreme form of empiricism, one that requires knowledge to be based on beliefs that are justified solely by experience. There are also more moderate forms that take the empirical base to include beliefs that are partly based on experience. An alternative way of handling this point would be to restrict the empirical base to those external beliefs that are justified solely by experience, leaving others for the superstructure.

It is just as well that those considerations are not conclusive, for there are serious difficulties in resting empirical knowledge of the world on a purely phenomenal base. Despite centuries of strenuous effort, no one has succeeded in showing how knowledge of the public physical world can be derived from knowledge of one's own experience, at least if we confine ourselves to generally recognized modes of inference. It has been widely recognized at least since the time of Hume that if we try to base an inference from sensory appearances to external objects on an empirically established correlation between them, we cannot establish that the correlation holds unless we already have knowledge of each side of it (see Hume, D. §2). And how can we get knowledge of the external side without already having established some such correlations to go on? Some have tried to side-step this difficulty by arguing that our experience is best explained by supposing that it is due to public physical objects in the ways we usually suppose (BonJour 1985). But that argument has never been developed in a thoroughly convincing way. Finally, some have turned in desperation to phenomenalism, the view that physical object statements are to be analysed in terms of what experiences one would have under certain circumstances. To say that there is a car parked in front of my house is to say something about what sensory experiences a sentient subject would have under certain conditions (Lewis 1946). The hope of the phenomenalist is that if the physical world is not radically different in nature from sense experience, it will not be impossible to infer the former from the latter. But apart from problems that attach to even these inferences, the programme runs afoul of the fact, classically pointed out by Chisholm (1948), that when we try to give a phenomenalist interpretation of, for example, 'There is a car parked in front of my house', we cannot specify the conditions in which a subject would have the relevant experiences without using physical-object language to do so. For example, we must include in those conditions the physical orientation and physical condition of the subject. We have to presuppose what we are trying to analyse in order to give the analysis (see Phenomenalism).

3 A public empirical base

These considerations drive us back to taking external perceptual beliefs to be, at least in part, directly justified by sense experience. There are many ways of spelling this out. The major differences come from differences in the analysis of sensory experience. We can distinguish three traditional views on this:

(1) Sense-datum theory. It consists of immediate awareness of non-physical entities that are, so to speak, reifications of the ways external objects appear to our experience. Thus, on this view, a typical visual experience of a round, red ball would involve being directly aware of a round, red sense-datum, which is distinct from the ball itself in being non-physical and existing only as an object for sensory awareness (Price 1932).
(2) Theory of appearing. A sense experience is an awareness of an object (in veridical perception an external

object) appearing to one in a certain way (looking, sounding, tasting… a certain way).
(3) Adverbial theory. Sense experience should not be construed as the direct awareness of any object - internal or external. It is rather a way or mode of awareness, a way of being conscious. When I see a red round ball, my consciousness is a matter of sensing redly, roundly, and, perhaps, 'ball-ly' (Chisholm [1966] 1977).

It has been held that sense experience is to be understood as a process of acquiring perceptual beliefs or inclinations to such beliefs (Armstrong 1961). Others have advocated physicalist construals in terms of the stimulation of sense organs. But these innovations have not had much effect on empiricist epistemology.

One might think that on the sense-datum theory one could not suppose external perceptual beliefs to be directly justified by sense experience. For this theory postulates the awareness of an internal object that, so to speak, stands between the subject and the external object. Does that not imply that any beliefs about the external object would have to be based on beliefs about the sense datum? Not necessarily. Several of the most prominent sense-datum theorists in the first part of this century - G.E. Moore, C.D. Broad and H.H. Price - emphatically denied that any inference from sense-data to external objects is involved. Instead they maintained that when one forms the usual external belief upon becoming aware of a certain sense-datum, that belief is justified just by virtue of being so formed. This is, in effect, to take the belief to be justified by the sense experience in question.

In considering the accounts of direct empirical justification one gets on these different construals of sense experience it will be helpful to recognize that in every case we need to draw a connection between features of the sense experience and the content of the belief. A belief will be justified by an experience only if there is the right kind of 'match' between the two. The details of the match will vary, depending on the account of sense experience. The sense-datum theory will have to work out some way of 'projecting' characteristics of external objects from features of sense-data. No one has ever done this in a convincing way for a realist (non-phenomenalist) account of physical objects. With phenomenalism it is a different ball game, for there the only entities referred to even in external beliefs are sense-data. The other views of sense experience have an easier time of it here. Since the theory of appearing construes sense experience as a matter of the way objects (usually external objects) appear, there can be a direct match between what an object appears to be and what it is. If an object looks like a two-storey wooden house, one is justified in believing it to be a two-storey wooden house. The only complexity here comes from complete hallucinations - Macbeth supposing himself to see a dagger in front of him when there is no dagger there. The theory can deal with such cases by saying that one is justified in the perceptual belief that *X* is *P* if and only if it is just as if *X* appears to one as *P*. (To Macbeth it was just as if a dagger appeared before him, the handle towards his hand.) The adverbial theory does not have this problem, since it does not construe sense experience as consisting in some *object* appearing in a certain way. It can read the content of the belief directly off the way of sensing, assuming, as may not be the case, that it is intelligible to convert all perceivable features of external objects into *ways* of sensing.

The complexity involved in formulating principles of justification that relate belief content to experiential content is so staggering that more than one philosopher has sought to cut the Gordian knot by simply granting *carte blanche* to all perceptual beliefs (Chisholm [1966] 1977). To be sure, one cannot deny that some perceptual beliefs are ill formed, and even among those that are not some can be shown to be false. We must not forget the many contradictions between witnesses to automobile accidents, as well as the proverbial drunkard who 'sees snakes'. A great help at this point is the distinction between *prima facie* and unqualified justification. To say that a subject is *prima facie* justified in believing that *p* is to say that this belief will be justified provided there is nothing to invalidate that status - either sufficient reasons for regarding the belief as false or sufficient reasons for supposing that the justifying grounds do not do the job in this instance (see Knowledge, defeasibility theory of). If I have a visual presentation of an elephant sitting on my lawn, I am justified in supposing that there is an elephant on my lawn, unless I have sufficient reasons for supposing that there are no elephants in the vicinity, or sufficient reasons for supposing that my visual experience was produced in such a way as to make it an unreliable indication of what is before me. Thus we can reasonably hold that all perceptual beliefs are *ipso facto prima facie* justified, even though this status may be overridden in some cases (see Perception, epistemic issues in).

4 Problems about the superstructure

As we have been characterizing empiricism, it would seem to be committed to foundationalism, the doctrine that

all knowledge (justified belief) rests on a foundation of beliefs that are justified otherwise than by other beliefs, for example, by experience (see Foundationalism). The ‘empirical base’ of which we have been speaking is simply a special case of the ‘foundations’ of foundationalism. It is only a special case because there are other possibilities for foundations, for example, rationally self-evident truths. But remember that we have acknowledged forms of empiricism that do not restrict the empirical base to beliefs justified solely by experience. Do these forms count as foundationalism? Well, we can also recognize stronger and weaker forms of foundationalism along the same lines (BonJour 1985). Strong foundationalism holds that all knowledge rests on beliefs that are wholly justified by something other than beliefs. Weaker forms require of foundational beliefs only that they are at least partially justified by something other than beliefs. Thus a weaker empiricism will also be a weaker foundationalism.

Continuing in the foundationalist vein, an empiricist epistemology will include not only a doctrine of the empirical base, but also a doctrine of the ways in which other beliefs are justified by their relations to that base. Traditional accounts have concentrated on deductive and inductive inference. Any beliefs that can be deductively or inductively inferred from that base are, or can be, justified. How this works out depends on the scope of inductive inference. If it is restricted to simple enumeration (inferring a generalization from instances), much of what we ordinarily consider to be empirical knowledge will fail to pass the test. Consider testimony: much of what we think we know has been acquired by taking someone’s word for it. Are we always or usually in possession of inductive evidence that the testifier is reliable? That is, have we checked out the person’s testimony in a sufficient number of cases and found it to be usually accurate? Obviously not. With most of the information we glean from books we have no evidence worthy of the name for the reliability of the author. We simply take it that the author is to be trusted unless we have reason to the contrary (see Testimony). Here too we give *prima facie* credence to certain beliefs, supposing them to be justified in the absence of sufficient reasons to think otherwise. Something similar can be said of the arguments to the best explanation that we constantly employ in a variety of contexts, for example, in arriving at an explanation of Jim’s recent unfriendliness towards me. Once again we take the fact that this seems to us the best explanation of the empirical facts in question to justify us in accepting it, even though, in most cases, we lack any significant deductive or inductive reasons for that acceptance (see Inference to the best explanation). Thus, if empiricism is to be at all plausible, it will have to recognize modes of building up the superstructure other than the traditional deductive and enumeratively inductive modes (Chisholm [1966] 1977).

5 Criticisms of empiricism

Criticisms of empiricist epistemology have mostly been of two types. First, there are areas of generally accepted knowledge that seem not to be accounted for by empiricism. Most prominently and most obviously, there is a priori knowledge, knowledge based on something other than experience (see A priori). The least controversial examples of this are logic and mathematics. To take a simple example, it seems for all the world as if our knowledge that ‘2 + 2 = 4’ does not rest at all on sense experience. It seems that we can know this to be true just by considering the proposition. The proposition is *self-evident*. There is no need to support it by empirical evidence, nor could it be overthrown by empirical evidence. If we seem to perceive two apples and two more apples making a sum of five apples rather than four, we would reject the supposed perception rather than the arithmetical truth. Other empirically recalcitrant areas include high-level theory in science, aesthetic knowledge and religious knowledge. But perhaps these latter cases can be handled by sufficiently extended ways of getting the superstructure from the base (high-level theoretical science) or by recognizing modes of justifying experience other than sense experience (aesthetic and religious experience). Still, logic and mathematics remain a stumbling block.

Some empiricists, like John Stuart Mill, have sought to show that mathematical knowledge, contrary to first impressions, rests on empirical evidence after all (see Mill, J.S. §§2-4). But a more common empiricist tack in the twentieth century has been that such knowledge is a matter of tracing out the logical implications of the meanings of the constituent terms. We know that ‘2 + 2 = 4’ just by virtue of realizing that its truth follows from what is meant by ‘2’, ‘Čplus;’, ‘Čequals;’ and so on. We know that ‘p’ logically follows from ‘p and q’ just because of what is meant by ‘and’ (Ayer 1936). But how does this show it to be *empirical* knowledge? It would seem that knowledge that owes its status to our grasp of the meanings of words is as far from being supported by *experience* as knowledge of self-evident propositions. The answer is that those who take this line do not suppose themselves to have shown that the knowledge in question is empirical, but rather that it is not knowledge ‘of the world’, not knowledge of what things are like independent of our conceptual arrangements. They take this line to imply that

so-called logical and mathematical knowledge is restricted to the consequences of the way we conceptualize the world, and hence not the sort of thing we should expect to be based on experience. In the most radical version of this position, the claim is that this (so-called) knowledge falls outside the empiricist net because it is not really knowledge at all.

The second criticism is of an internal kind. Whereas the first objection was that there are areas of knowledge that empiricism cannot accommodate, the second objection is that even on the empiricist's home field knowledge claims rest, in part, on non-empirically based principles. The most widely advertised example concerns induction. Many philosophers have concluded that we cannot rationally infer generalizations from instances without assuming some principle of regularity. Suppose we have examined 5,000 samples of copper all of which are ductile. How does that warrant us in inferring that copper is always (or even almost always) ductile? How do we know that the next 5,000 samples will not fail to exhibit ductility? When we make inferences like this, are we not assuming some such general principle as that 'Regularities that hold in a large and varied sample will hold universally', or 'The future will resemble the past', or 'Properly chosen samples are representative of the whole class of which they are samples'? And are such principles themselves justified by experience? If we were to suppose they are, would that not require us to assume such principles in order to validate the inference? And that would make the empirical justification circular. Hence it seems that empirical induction depends for its validity on principles that cannot be empirically justified. And that would seem to be an absolute limit on the extent to which we can take knowledge, even in the 'empirical' sphere, to be wholly justified by experience (Russell 1948) (see Induction, epistemic issues in).

Encyclopedists, 18th-century

The Encyclopédie, ou dictionnaire raisonné des sciences, des arts et des métiers was published in seventeen folio volumes (about 20 million words) between 1751 and 1765, accompanied by eleven volumes of engravings (1762-72). Its chief editor was Diderot, with D'Alembert acting as co-editor for the first seven volumes. The work was an expression of the Enlightenment belief in improvement through knowledge.

From the outset the *Encyclopédie* attracted hostile criticism, especially from ecclesiastical circles; publication was halted twice and the last ten volumes had to be collected by subscribers from outside Paris. Because of its comprehensive scope, the wide range of its contributors, and the prominence which it owed as much to its critics as its supporters, the work came to be regarded as an embodiment of the French Enlightenment. Numerous editions (and volumes of extracts) were published in the 1770s and 1780s, as well as four supplementary volumes and two volumes of indices.

In his article 'Encyclopédie' in volume V (1755), Diderot expressed an intention 'of changing the general way of thinking'; in his *Discours préliminaire* to volume I (1751), D'Alembert provided the fullest account of the principles guiding this ambition. They were epitomized by the phrases 'esprit philosophique' or 'esprit systématique', by which was meant a critical, enquiring, rational approach, opposed to prejudice, obscurity, superstition, intolerance and dogmatism (whether that emanating from established institutions or that evident in the 'esprit de système' of a priori philosophical doctrines). The empirical method of Locke, the scientific principles of Newton, and the practical benefits of knowledge advocated by Francis Bacon, were held up as models; the writings of Bayle, Fontenelle and Montesquieu were significant influences. The practical application of thought, in terms of both social reform and the mechanical arts, received particular emphasis; a humanitarian concern and a desire for freedom (intellectual, civil, economic, political) were recurring themes, although the work was not politically radical. The philosophical articles were not notable for their originality, (although the occasional discussion of materialist ideas was seen as dangerously new by some); many took the form of a historical survey, written by Diderot but drawing heavily on J.J. Brucker's *Historia critica philosophiae*.

The title-page announced that the *Encyclopédie* was written by 'une société de gens de lettres', over a hundred and thirty of whom have been identified. Apart from contributions from Voltaire, who wrote over forty articles of minor interest, and some by figures who later became famous - such as the editors themselves, Rousseau, Turgot, d'Holbach, Quesnay, or Marmontel - most were by individuals who were little known or of whom we otherwise know nothing (see Rousseau, J.-J.). Generally speaking they seem to have been experts in their fields: professional men, academicians, civil servants, scientists, doctors, men of letters, engineers, manufacturers, and so on. Almost a quarter of the work was written by one dedicated, indefatigable and (regrettably) undistinguished contributor, the Chevalier de Jaucourt. The diversity of these figures, the variety of views expressed and the unevenness of the articles prevent any easy categorization of these writers, but their participation in the enterprise itself demonstrated a widespread faith in the power of ideas to bring about human improvement.

Encyclopedists, medieval

The modern encyclopedic genre was unknown in the classical world. In the grammar-based culture of late antiquity, learned compendia, by both pagan and Christian writers, were organized around a text treated as sacred or around the canon of seven liberal arts and sciences, which were seen as preparatory to divine contemplation. Such compendia, heavily influenced by Neoplatonism, helped to unite the classical and Christian traditions and transmit learning, including Aristotelian logic, to the Middle Ages.

Writers in the encyclopedic tradition include figures such as Augustine and Boethius, both of whom were extremely influential throughout the medieval period. Other important writers included Macrobius, whose Saturnalia spans a very wide range of subjects; Martianus Capella, whose De nuptiis Philologiae et Mercurii (The Marriage of Philology and Mercury) covers the seven liberal arts and sciences; Cassiodorus, who presents the arts as leading towards the comtemplation of the heavenly and immaterial; and Isidore, whose Etymologies became one of the most widely referred-to texts of the Middle Ages. These writers also had a strong influence which can be seen later in the period, particularly in the Carolingian Renaissance and again in the twelfth century.

1 Learned compendia and the encyclopedic tradition

The classical world produced nothing like the modern encyclopedia with its universal range and disconnected entries in alphabetical order. Instead, ancient scholars preferred to unify their knowledge by literary or philosophical means. By the first century BC the term 'encyclopedia' was often used, but it generally denoted a set of interconnected disciplines fit for upper class freemen (hence 'liberal') and propaedeutic in nature. The philosophers might see such disciplines as leading the mind from the material to the immaterial world, and thence to metaphysical philosophy. For most, the set included both mathematical and linguistic arts. With much fluctuation, there evolved a canon of seven interrelated liberal arts and sciences: grammar, rhetoric and dialectical logic (the medieval trivium), and arithmetic, geometry, music and astronomy (the medieval quadrivium). During the first three centuries AD, Middle Platonist and Neoplatonist philosophers strongly influenced the solidifying of this canon; indeed, it has been seen (controversially) as primarily their invention (Hadot 1984) (see Neoplatonism; Platonism, early and middle).

Various types of learned compendium existed, and it is possible to distinguish three particular types or genres. Genre A can be described as miscellaneous information, presented haphazardly, perhaps in the attractive and memorable dialogue form, as a gentleman's 'learned baggage' (to use Macrobius' phrase) and handbook of civilized conversation. An example is the *Attic Nights* of Aulus Gellius, written in the second century AD. In genre B, information is organized by disciplines, whether in a sequence of treatises or as a unitary work. Varro (116–-27 BC) probably composed an encyclopedic sequence of volumes on the seven arts and sciences, with medicine and architecture added. Varro allegedly saw the mathematical four as leading to contemplation of the immaterial; in this he may have been influenced by Neopythagorean philosophy (see Neo-Pythagoreanism). In the first century AD, in his *Natural History*, the elder Pliny united his subject by themes of nature's divinity and human partnership with it; this allowed expansion into a wide range of information.

In the culture of late antiquity, dominated by the grammarian, a third type of compendium developed. In genre C, compendia were centred around some revered text, classical or biblical. These texts, which were often seen as inspired, could be allegorically interpreted and used as a source of cosmological, spiritual and metaphysical wisdom. Isidore, for example, drew extensively for his encyclopedia on both the *Hexaemeron (Commentary on Genesis)* of Ambrose (AD 339-97) and the commentaries on Vergil of Servius (*fl. c.*AD 400), whom Macrobius depicted as the model grammarian. To understand such sacred texts, encyclopedic learning, especially the skill in literary analysis owed to grammar and rhetoric, was seen as necessary and the texts themselves might serve as educational exemplars (see Patristic philosophy).

2 Augustine

As a young man, Augustine was strongly influenced by the Neoplatonists. Following his conversion to mainstream Christianity, he proposed a sequence of works on the seven arts and sciences, perhaps substituting philosophy for

astronomy. He saw these as propaedeutic to a theology of Christian Neoplatonist type Hadot 1984). He also increasingly saw them as handmaids to biblical exegesis (see his very influential *De doctrina christiana (On Christian Instruction)*). He apparently completed works on grammar and music only (the latter in dialogue form), but his *De civitate Dei (The City of God)* transmitted a vast range of learning in its replies to polytheists and pagan Neoplatonists.

3 Macrobius

Macrobius' *Saturnalia*, written *c*.AD 430, but set in the 380s, belongs partly to genre A. In their form, and as an exemplar of scholarly manners, these prandial conversations between Roman gentlemen owe much to Cicero and Aulus Gellius. However, their core (Books III-VI) consists of discussions of Vergil, seen as universally learned and inspired. Partly through and around these discussions, Macrobius transmitted views and information on literary style, allegorical technique, pagan ritual and theology, astronomy, physiology, etymology and general antiquarian topics.

For Macrobius, the other three inspired authors were Homer, Plato and Cicero. His Platonizing commentary on *The Dream of Scipio* (from Cicero's *Republic*) helped to transmit classical cosmological science to the Middle Ages, integrating it with Neoplatonist theology. This work is also important for its numerology, classification of the virtues and presentation of Platonist and Aristotelian disputes on the nature of the soul. It owed much to commentaries on Plato's *Timaeus* and *Republic* by Porphyry, and notably influenced the thirteenth-century encyclopedist Vincent of Beauvais.

4 Martianus Capella

Like Macrobius, Martianus was probably a pagan; he wrote at Carthage, perhaps around AD 470. His *De nuptiis Philologiae et Mercurii (The Marriage of Philology and Mercury)* belongs partly to genre B, systematically expounding and summarizing the Varronian canon of arts and sciences (omitting medicine and architecture). However, the work (a 'Menippean' mixture of prose and verse, like Varro's satires) also depicts, in an allegorical myth, the Neoplatonic apotheosis of the learned human soul, which returns to its heavenly home to become the bride of a god; on this marriage the arts and sciences attend as bridesmaids. Thus Martianus audaciously improved on Macrobius by creating his own sacred text: ' With its description of the kosmos, the fall and ascent of the soul, theurgical initiation, and an apotheosis, the work can be seen as a summa of pagan knowledge, religious and secular' (Shanzer 1986: 28).

Paradoxically, this was a work which, in terms of both form and content, had a profound influence on the Christian Middle Ages. In the ninth century, Johannes Scottus Eriugena drew extensively on it for his cosmology; in the tenth century, Gerbert of Aurillac made much use of the books on the quadrivium. Its influence was especially strong on the Platonists and cosmographers associated with the twelfth-century School of Chartres (see Chartres, School of). Alan of Lille owed much to it in his *De planctu naturae*, and also in his *Anticlaudianus*, a summa of the seven arts and sciences which depicts the ascent of Phronesis, with their help, to the Empyrean. Bernard Of Tours similarly has an ascent of Natura in his Menippean *De mundi universitate*.

Book IV of *De nuptiis*, on dialectic, was especially influential in the ninth to eleventh centuries. Martianus' logic was basically Aristotelian and syllogistic, depending much on Porphyry's *Isagoge*, which he perhaps knew in the fourth-century translation by Marius Victorinus; he may well have used a *Perihermeneias* (perhaps that of Apuleius in the second century) for categorical propositions, and the categorical syllogism. He was also affected by Stoic development of the hypothetical syllogism and by Stoic propositional logic, derived ultimately from Varro (see Stoicism). Like Boethius and Cassiodorus, Martianus transmitted the so-called *logica vetus* (old logic); this was partly superseded during the twelfth century by the *logica nova* (new logic), through the discovery of more sophisticated works of Aristotle (see Aristotelianism, medieval; Language, medieval theories of; Logic, medieval).

5 Boethius

Boethius, writing in sixth-century Italy, was much influenced by the Neoplatonism of Macrobius and the fifth century Alexandrians. He planned, but never finished, complete translations of Plato and Aristotle and a series of introductions and translations for the seven arts and sciences; he is therefore another encyclopedic author. His

Institutio arithmetica (Introduction to Arithmetic) and *Institutio musica (Introduction to Music)* survive, as do a commentary on Cicero's *Topics*, translations and commentaries for Porphyry's *Isagōgē* and Aristotle's *Prior Analytics*, *Categories* and *Perihermeneias*, and translations of Aristotle's *Topics* and *Sophistic Refutations*. In five treatises, he gave his own introduction to Peripatetic logic.

Eriugena, Gerbert of Aurillac, Abbo of Fleury, Anselm and Abelard all owed much to Boethius. His logic influenced the debate between realists and nominalists, and remained popular until the end of the fifteenth century. He also transmitted Pythagorean musical theory and Euclidean geometry.

6 Cassiodorus

Boethius' kinsman Cassiodorus, writing also in the sixth century, was a rhetorician rather than a philosopher and was an encylopedist in all three genres. His *Variae* (letters drafted for barbarian monarchs) digress into a wide range of learning offering a model of cultivated discourse between ruler and subject, and were exploited later in the Middle Ages. His *Expositio Psalmorum (Exposition on the Psalms)* is partly conventional exegesis, but also developed the Psalms for Christians as an encyclopedic exemplar of the arts and sciences, especially rhetoric.

Cassiodorus' *Institutiones*, partly an intellectual rule for his monastery of Vivarium, were also meant for a wider audience, superseding a project for a Roman school of Christian higher education. Book I is a kind of patristic and monastic encyclopedia. It gives an expanded bibliography of biblical texts, commentaries and works of relevant theology, as well as advice on exegesis, a list of church councils and information on history, geography, medicine, gardening and textual copying. Book II, which achieved a separate and wider circulation, is devoted to the seven arts and sciences. Like Augustine, Cassiodorus regarded these as essential to scriptural study; he also presents them as leading the soul towards the heavenly and immaterial, to the point where the Bible will deepen awareness of God. He treats the seven methodically, analysing and summarizing their salient points and advising on further reading. His canon is that of Varro and Martianus Capella, but he owes something also to the tradition of the fifth century Neoplatonists (especially, perhaps, Ammonius). From the latter he derives the order of his treatment, his influential distinction between the arts of the trivium and the disciplines of the quadrivium (the former deal with contingent matters, the latter with necessities) and his analysis of the subjects of philosophy: the disciplines belong to doctrinal or mathematical philosophy, which is in turn a branch of speculative philosophy.

His section on dialectic is based partly on the translations and commentaries of Boethius and Marius Victorinus, but perhaps also on Ammonius' commentary on Porphyry's *Isagōgē. Institutiones* II proved a highly valuable handbook in the early Middle Ages, and specially influenced two major figures of the Carolingian Renaissance, Alcuin and Hrabanus Maurus. The latter's *De institutione clericorum* integrated the arts and sciences into clerical education, as Cassiodorus had done (see Carolingian Renaissance).

7 Isidore of Seville

Isidore's *Etymologies* or *Origins*, written in the early seventh century, was a new - though still grammar-based - departure, organizing knowledge around the histories and definitions of individual words. Indebted ultimately to Stoic theories of etymology, but more directly to Augustine's remarks on semiotics (especially in *De doctrina Christiana* II), Isidore assumed that the name of a thing gives a key to its nature. On this principle (partly rational, but also reflecting Neo-Pythagorean and biblical mysticism) he founded a twenty-book compendium, encyclopedic in range even by modern standards. Only the first four books deal with the seven arts and sciences (medicine is added as a second philosophy, healing the body as philosophy does the soul), and the dictionary method precludes extensive expositions.

Following the tradition, Isidore sees the canon as steps to divine contemplation. From Book V onwards the work is less systematic, though by no means random in construction. Isidore follows trains of thought in which (for example) Christian studies (Books VI-VIII) conclude with a catalogue of heresies; heresies suggest pagan philosophies, philosophies suggest classical poetry and poetry suggests sibyls, mages and diviners. Book II, on rhetoric and dialectic, is based mainly on Cassiodorus, but Isidore made additions: there is a section on law, based on Tertullian, and another on opposites (ultimately Aristotelian, and also treated by Martianus Capella). Etymologies in this book yielded useful translations of Greek technical terms.

Second-hand Stoicism influenced Isidore's views on cosmology and morality (see Stoicism). Although

condemning Epicureanism, he retained the atomic theory, and extended it to numbers and language (Book XIII). He gave a brief survey of ancient philosophy (Book VIII), valuable despite its crudities. Also valuable was his exclusion of Christian theology and revelation from his logical definitions, and his strong assertion of the worth of dialectic (Book II); he affirmed the continuing relevance of philosophy, despite its dangers to the Christian (Books IV and VIII). The simple Latin, brief entries and lists of contents made the *Etymologies* ideal for reference; its survival in over 1,000 manuscripts attests its popularity. Curtius (1953: 23) has called it the basic book of the entire Middle Ages. Hrabanus Maurus adopted Isidore's method, and much of his contents, in his encyclopedia *On the Nature of Things*.

8 Conclusion

Late antiquity was a period of translations, florilegia, abridgements and other short guides to a variety of disciplines. As Boethius saw, these were vital when Greek east and Latin west were drifting apart, and educational institutions declining. It was also a time of tension between Christianity and the classical tradition. In the preservation of learning and eventual combination of the two roads to wisdom, the encyclopedists, pagan and Christian, played an essential part, thanks largely to the adaptability and spiritual attractions of the Neoplatonic philosophy which so strongly influenced their subject matter.

Shanzer, D.R. (1986) *A Philosophical and Literary Commentary on Martianus Capella's De Nuptiis Philologiae et Mercurii*, Book I, Berkeley, CA: University of California Press.(As an introduction to Martianus, less comprehensive but more intelligent than Stahl and Burge's first volume.)

Engels, Friedrich (1820-95)

Until the 1970s the most influential framework for understanding Marx's career and ideas was the one established by Engels. This framework was crucially related to his understanding of philosophy and its supposed culmination in Hegel's systematic and all-encompassing idealism.

Engels claimed that Marx had grounded Hegel's insights in a materialism that was coincident with the physical and natural sciences of his day, and that Marx had identified a dialectical method applicable to nature, history and thought. With respect to history, Marx was said to have formed a 'materialist conception', from which his analysis of capitalist society and its 'secret' of surplus value were derived. Together these intellectual features were the core of the 'scientific socialism' which, Engels argued, should form the theory, and inform the practice, of the worldwide socialist or communist movement. This was to abolish the poverty and exploitation necessarily engendered, he claimed, by modern industrial production.

Philosophically the tenets of dialectical and historical materialism have been defended and modified by orthodox communists and non-party Marxists, and expounded and criticized by political and intellectual opponents. The three laws of dialectics, and the doctrine that history is determined by material factors in the last instance, have been attacked as tautologous and indeterminate. Engels's view that scientific socialism is a defensible representation of Marx's project has also been challenged by textual scholars and historians.

1 Life and works

Engels rightly described himself as an 'autodidact in philosophy', and neither planned nor realized a career as a philosopher in his lifetime. Yet his works represent the founding texts of Marxism and of Marxist philosophy, in that they set an authoritative context through which to interpret the ideas of Karl Marx in a specifically philosophical way.

Born into a wealthy Rhineland family, and growing up amidst the disruption of rapid industrialization, the teenage Friedrich embarked on a paradoxical career. All his life he was reluctantly associated with the family's business interests, though politically he sympathized with the plight of the industrial working classes. Pursuing his political interests as a revolutionary populist required him to address intellectual elites and doctrinaires, particularly those within the burgeoning socialist movement and tiny communist parties. Yet the issues addressed in those works became ever more rarified and philosophical, despite the scorn that he always evinced for 'mere' philosophers and dabbling cranks, and his enthusiasm for political action.

Most paradoxically of all, Engels pronounced himself 'junior partner' to Marx, yet for many years the only way to identify, explicate and defend the *philosophical* content of Marx's work was through *Herrn Eugen Dührings Umwälzung der Wissenschaft* (*Anti-Dühring*), *Socialisme utopique et socialisme scientifique* (*Socialism: Utopian and Scientific*) and *Ludwig Feuerbach und der Ausgang der klassischen deutschen Philosophie* (*Ludwig Feuerbach and the End of Classical German Philosophy*), all written by Engels and published under his name alone. The claim that those works represent the views of Marx rests on retrospective textual exegesis, theories of 'partnership' and 'division of labour' between the two, and negative 'evidence' that Marx, who was Engels's economic dependent from the 1850s until his death in 1883, had opportunities to repudiate what Engels was saying. Engels himself contributed to this narrative, establishing his own works as the authoritative interpretation of Marx. Hence his self-description as 'second fiddle' is in reality somewhat paradoxical.

Bizarrely, Engels is also given credit for 'assuming paternity' for the illegitimate son of the Marx family's housemaid, supposedly to save Marx embarrassment and his wife the scandal. But the documentary evidence for this tale is highly suspect, and the view that paternity of this child was an issue for anyone at all before the 1960s, when the story first surfaced, rests on reading this lurid narrative back into the ambiguities of contemporary correspondence (Carver 1989: 162-71).

Engels had the image of a lifelong bachelor in public and a discreet bohemian in private, and his successive liaisons with the working-class Burns sisters (Mary and 'Lizzie') are well attested. Yet they now seem to fit all too easily into the nineteenth-century pattern wherein bourgeois males could 'keep' women of an inferior class in the suburbs or employ them in a respectable function as housekeeper, whilst presuming in every way on their

economic dependence. Engels married ‘Lizzie’ only when it was clear that she was dying and could not be Mrs/Frau Engels in his Anglo-German milieu, nor survive him as a claimant on his estate. These liaisons were childless, and it is likely that both women were lifelong illiterates, or nearly so.

Engels himself was an accomplished writer from his early twenties in German and English, fluent in French, and later a student and correspondent in numerous other languages. His library and papers, including the collection of manuscripts and other materials inherited from Marx, represented an important intellectual resource for the socialist and communist movement from his death until the dissolution of Soviet-style communism in the 1980s, not least the notebooks posthumously published as *Dialektik der Natur* (*The Dialectics of Nature*), from which an ‘official’ philosophy of science was derived (see Dialectical materialism).

2 Political theory

By the time he was nineteen, Engels’s intellectual and political interests had moved from a heady combination of revolutionary liberalism and romantic nationalism to the Young Hegelian perspective then current in the universities, though he was never officially able to be a student. From a twentieth-century perspective this movement seems an intellectual cabal, but Engels’s apprehension of these debates was overwhelmingly political. In a regime where politics itself was almost wholly an illegitimate activity, any form of criticism was by definition subversion and inevitably confined to a small circle of writers, publishers and readers.

Engels can be distinguished from others in the school by his unusual interest in modern technology and applied sciences, and in his preoccupation with the industrial working classes, existing and prospective. Within a short time he was contributing to the *Rheinische Zeitung*, most notably on the social science of political economy, as yet little appreciated in Germany, and on attempts to discern its place within Hegel’s overall system. Thus Engels first met the earnest Dr Marx and the communist Moses Hess on a brief visit to the editorial collective at Cologne in 1842, whilst *en route* to a further posting with the family manufactures at Manchester.

In England Engels wrote in both German and English on ‘the social question’ and the politics of class conflict, giving particular attention to socialism or communism (the terms were largely indistinguishable then). This was conceived as a system of cooperative ownership of productive resources and an egalitarian, non-monetary system of distribution applicable to society at large, combined with institutions for democratic decision-making. Engels’s *Umrisse zu einer Kritik der Nationalökonomie* (*Outlines of a Critique of Political Economy*) argued that a developing rationality in history could be discerned in both economic theory and practice. Applying a Hegelian dialectic of successive negations to the concepts ‘free trade’ and ‘competition’, he derived the necessity of worsening economic crises as his result, and the tenets of communism and the politics of class struggle as a resolution. Moreover in *Die Lage der arbeitenden Klasse in England* (*The Condition of the Working Class in England*) he produced an impassioned documentary and eyewitness survey of proletarian poverty and exploitation in modern industry.

On his return to Germany in 1844 Engels continued his career as a political agitator and socialist pamphleteer, this time in particular association with Marx, and the two produced three collaborative works: *Die heilige Familie* (*The Holy Family*) (by Engels and Marx, though with separately signed chapters), the manuscript *Die deutsche Ideologie* (*The German Ideology*) (posthumously published as the work of Marx and Engels), and their joint, though unsigned, masterpiece *Manifest der kommunistischen Partei* (*Manifesto of the Communist Party*).

During the revolutionary events of 1848-9 Engels assisted Marx, who had assumed editorship of the *Neue Rheinische Zeitung* in Cologne. Although Engels took advantage of the need to flee political repression from resurgent monarchists by making a walking tour through Burgundy in the autumn of 1848, he also saw active service in the spring of 1849 as liberal insurgents retreated in a more or less orderly way to the Swiss border. Making his way to England, Engels settled gradually but firmly into a life away from Germany, from partisan politics in either country, and from direct engagement with economic theory or social conditions, other than through a role, largely self-assumed, as publicist, popularizer and eventually editor for Marx.

3 Scientific socialism

Philosophically, Engels’s distinctive contributions were the terms ‘materialist conception of history’ and the ‘laws of dialectics’, which were assigned to Marx but explicated in various reviews, letters, introductions and texts. The

assignment of these terms to Marx is itself questionable, and the explications by Engels are neither as full nor as tightly written as his reputation suggests.

Marx formulated and employed an ‘outlook’, occasionally self-identified as ‘materialist’ (in opposition to both idealism and ‘traditional’ materialism), and used terms such as ‘science’, ‘law’ and ‘dialectic’ in his works (though much more rarely than most commentaries suggest). But it was Engels who insisted that Marx’s presuppositions included a matter-consciousness dichotomy, that his works were part of a system of Hegelian proportions, that his politically engaged social science was inclusive of the natural sciences of the day (including Darwinian biology as well as physical chemistry), and that a methodology derived from Hegel’s presumed ‘dialectic’ was crucial for Marx and for understanding his achievements.

In Engels’s commentaries, Marx’s ‘materialist conception of history’ included both the quoted view that ‘the mode of production of material life conditions the social, political and intellectual life-process in general’, and the gloss that ‘political action and its results originated in material causes’. Thus Marx’s ‘guiding thread’ was said to be the ‘great law of motion in history’, but in Engels’s version it emerged with a further layer of philosophical ambiguity. Engels’s qualifications - that ‘the production and reproduction of real life’ is the ‘ultimately’, but not the only, ‘determining element’ in history - could never allay the additional difficulties that he imposed on what were already problematic, and arguably for Marx, quite marginal formulations.

The ‘laws of dialectics’ assigned to Marx were formulated by Engels as reworkings of Hegel’s insights into a modern ‘science of interconnections, in contrast to metaphysics’. He suggested three: ‘transformation of quantity into quality and vice versa’, ‘interpenetration of opposites’ and ‘negation of the negation’. He described these as causal and invariable laws of motion forcing their way through the innumerable changes that can be observed in natural phenomena, human history, and ‘thought’ or logic, and maintained that they were validated by deduction. The circularity of such observations and the tautologous character of such laws were not apparent to Engels, and his more extravagant claims to link those ideas to a Marxian ‘system’ were not in fact published until after Marx’s death (Carver 1983: 129-41).

Engels’s ‘scientific socialism’ grounded the intellectual wing of the socialist and communist movement firmly in German philosophy, which he presumed had culminated in Hegel. The overarching project of his life was to link the world of progressive politics with the truths that he believed could be discerned from a philosophical system spanning the material, social and conceptual worlds, conceived developmentally. Among those truths, he alleged, was Marx’s concept of ‘surplus value’. This and other truths identified by Marx were said by Engels to be critical elements in a revolutionary political strategy. But Engels was not himself expert at the practicalities of getting from philosophical ideas to political action, nor was his philosophy capable of generating a concept of human agency that was philosophically defensible or politically useful.

TERRELL CARVER

List of works

Engels, F. (1844) *Umrisse zu einer Kritik der Nationalökonomie*, trans. M. Milligan, *Outlines of a Critique of Political Economy*, in K. Marx and F. Engels, *Collected Works*, London: Lawrence & Wishart, 1975, vol. 3, 418-43.(Pioneering attempt to subject political economy to philosophical analysis.)

Engels, F. (1845) *Die Lage der arbeitenden Klasse in England*, trans. F. Kelly-Wischnewestzky, *The Condition of the Working Class in England*, in K. Marx and F. Engels, *Collected Works*, London: Lawrence & Wishart, 1975, vol. 4, 295-583.(A survey, still very readable, of the horrors of early nineteenth-century industrialization.)

Engels, F. (1878-9) *Herrn Eugen Dührings Umwälzung der Wissenschaft*, trans. E. Burns, *Anti-Dühring*, in K. Marx and F. Engels, *Collected Works*, London: Lawrence & Wishart, 1987, vol. 25, 5-309.(Polemical work incorporating Engels’s influential interpretation and defence of Marx.)

Engels, F. (1880) *Socialisme utopique et socialisme scientifique*, trans. *Socialism: Utopian and Scientific*, in K. Marx and F. Engels, *Selected Works in One Volume*, London: Lawrence & Wishart, 1968, 375-428.(Three chapters of *Anti-Dühring* revised, published as a pamphlet and very widely translated and circulated.)

Engels, F. (1884) *Der Ursprung der Familie, des Privateigentums und des Staats*, trans. *The Origin of the Family,*

Private Property and the State, in K. Marx and F. Engels, *Selected Works in One Volume*, London: Lawrence & Wishart, 1968, 449-583. (Engels's attempt to account for the origin of women's oppression and the evolution of private property in prehistory by using a social Darwinian theory of sexual selection as well as gendered explanations of economic development.)

Engels, F. (1886) *Ludwig Feuerbach und der Ausgang der klassischen deutschen Philosophie*, trans. *Ludwig Feuerbach and the End of Classical German Philosophy*, in K. Marx and F. Engels, *Selected Works in One Volume*, London: Lawrence & Wishart, 1968, 584-622.(First published as a review, this is a history of German philosophy, placing Marx's materialism at its culmination and identifying it as an inversion of Hegelian idealism and arguing its coincidence with natural science.)

Engels, F. (1925) *Dialektik der Natur*, trans. C. Dutt, *The Dialectics of Nature*, in K. Marx and F. Engels, *Collected Works*, London: Lawrence & Wishart, 1987, vol. 25, 311-588.(Notes comprising a philosophical analysis of the subject matter and methods of nineteenth-century natural science, including the 'laws of dialectics'.)

Engels, F. and Marx, K. (1845) *Die heilige Familie*, trans. R. Dixon and C. Dutt, *The Holy Family*, in K. Marx and F. Engels, *Collected Works*, London: Lawrence & Wishart, 1975, vol. 4, 5-209.(An attack on romantic, utopian and philosophical socialists of the 1840s, but incorporating interesting early formulations of Marx's 'outlook'.)

Engels, F. and Marx, K. (1932) *Die deutsche Ideologie*, trans. W. Lough, *The German Ideology*, in K. Marx and F. Engels, *Collected Works* vol. 5, London: Lawrence & Wishart, 1976, 19-581.(Foundational manuscript, still not accessible in a properly edited version, nor adequately interpreted yet as an integrated work, but essential reading as an important exposition of Marx's 'outlook' in Part One.)

Engels, F. and Marx, K. (1848) *Manifest der kommunistischen Partei*, trans. S. Moore, *Manifesto of the Communist Party*, in K. Marx and F. Engels, *Collected Works*, London: Lawrence & Wishart, 1976, vol. 6, 477-519.(Still the best introduction to Marx's 'outlook', particularly the centrality of class struggle, and innocent of Engels's later interpretive framework, save in the footnotes.)

Engineering and ethics

Engineering ethics is that form of applied or professional ethics concerned with the conduct of engineers. Though engineers do many different things, they share a common history, which includes codes of ethics. Most codes explicitly declare public health, safety and welfare to be 'paramount'. Many questions of engineering ethics concern interpretation of 'public', 'safety' and 'paramount'. Engineers also have important obligations to client and employer, including confidentiality, proper response to conflict of interest, stewardship of resources, and honesty (not only avoiding false statements but volunteering certain information). Each engineer also has obligations to other engineers and to the profession as a whole.

1 The profession of engineering

'Engineering' as an honorific term suggesting both precision and success is often used where it does not belong. The pyramids are sometimes described as 'works of engineering', though engineers had nothing to do with them. 'Social engineering', 're-engineering' and even 'genetic engineering' - though technologies or applied sciences - are no more engineering than architecture or medicine is.

What, then, is 'engineering'? Unfortunately, there is no wholly satisfactory answer. It is, of course, what engineers do, but engineers do many things. They design machinery, chemical plants, harbours, bridges, office buildings, electrical grids, and other complex systems, manage their construction, oversee their operation, and plan their disposal. Though other occupations may do such things too (for example, architects also design buildings), engineers differ from these others in how they do it. Engineering is a certain way of doing such things. This way of doing things has a history; it is that history, rather than any abstract idea, that defines engineering.

The English word 'engineer' comes from French. The first people to be called 'engineers' were soldiers associated with 'engines of war' (such as cannons and siege towers). They were engineers only in the sense that they operated (or otherwise worked with) an 'engine' (that is, a complex device for some useful purpose). In 1676, the French organized these 'engineers' into a special unit, the *corps du génie*. Within two decades, the *corps* was known all over Europe for unusual achievements in military construction. When another country borrowed the French word 'engineering' for use in its own army, it was for the sort of activity the *corps du génie* engaged in.

At first, the *corps du génie* was more like an organization of masters and apprentices than a modern profession. Only during the 1700s did the French slowly come to understand what they wanted in an *officieur du génie* and how to get it by formal education. By the end of the 1700s, they had a curriculum from which today's engineering curriculum differs only in detail; they had also invented engineering as an occupation distinguished from that of other builders by its knowledge of modern physics, chemistry and mathematics, its skill in organization, and its concern with utility rather than beauty, and from the sciences by its focus on making rather than knowing. Civilian engineering is a branch of this (originally) military tree.

So far, this is a history of an occupation. The history of a profession tells how people engaged in a certain occupation organized to hold each other to standards beyond what law, market, and morality would otherwise demand. The history of a profession is the history of organizations, standards of competence, and standards of conduct. For engineering, that history tells of a slow shift from granting membership based on connection with large construction projects, practical invention, or other technological achievements to granting it based on two more demanding requirements. One requirement - a certain sort of knowledge - is occupational. This requirement is now typically identified with a degree in engineering. The other requirement - a commitment to use that knowledge in certain ways (that is, according to engineering's code of ethics) - is professional (see Professional ethics).

2 Ethics and engineering

'Ethics' (in this context) can be used in three senses: (a) as a synonym for ordinary morality; (b) as the name of a philosophical study attempting to understand morality as a rational undertaking; or (c) as the name of certain special standards of conduct governing members of a group in virtue of their membership (see Morality and ethics §§1-2).

In the first sense, engineering ethics is the application of ordinary moral rules, principles, or ideals to circumstances involving engineering. Neither philosophers nor codes of professional ethics have more than an educational or heuristic role. In the second sense, engineering ethics consists of attempts to offer a reasoned understanding (a theory) of how ordinary morality should guide engineering. In this sense, engineering ethics is just a subdivision of moral theory ('philosophical ethics'). But in the third sense, engineering ethics resembles law. Just as a law (or legal system) applies only to certain moral agents, those within its jurisdiction, so engineering ethics would apply only to certain moral agents, engineers. And just as law includes the interpretation, application, and justification of particular laws, so engineering ethics would include the interpretation, application and justification of engineering's special standards. The philosophical contribution to engineering ethics (in this sense) resembles legal philosophy's contribution to law, more a sorting of concepts and arguments than an application of moral theory.

Formal codes of engineering ethics did not appear in England before the mid-1800s, in the United States before 1900, or in Germany before the 1950s. While many professions, especially law and medicine, make a commitment to the profession's code of ethics a formal requirement for admission, engineering has not, except for licensed Professional Engineers. Instead, the expectation of commitment reveals itself when an engineer is found to have violated the code of ethics. The defence, 'I'm an engineer but I didn't promise to follow the code and therefore did nothing wrong', is never accepted. The profession answers, 'You committed yourself to the code when you claimed to be an engineer.'

While engineering ethics (in our third sense) dates from the 1800s, its philosophical study (ethics in our second sense) dates only from the 1970s. The field is still taking shape, working out its relation with moral theory, philosophy of technology, and philosophy of the professions.

Engineering ethics does not yet have a settled place in the college curriculum. In philosophy departments, classes in engineering ethics are often called 'Moral Problems in Engineering'; in engineering departments, 'Issues in Professionalism'. A course in engineering ethics, whether taught in a philosophy or an engineering department, will cover much about the history and organization of engineering.

3 Topics in engineering ethics

One topic of engineering ethics is the status of the code of ethics itself. (There are, in fact, several codes, though differences are relatively small.) Is a code just a statement of what morality would require of engineers, code or no code, or does it demand more of engineers than morality does? If it demands more, on what basis, if any, can it claim obedience from engineers? Is the claim legal or moral? If moral, does it rest on an implicit promise or on some other moral consideration (see Promising)?

Almost any code of engineering ethics provides a good checklist of major topics of engineering ethics. We may divide the other topics into four large categories. The first category concerns obligations to the public. Though the first codes of ethics emphasized personal honour and loyalty to client or employer, today most emphasize the public health, safety and welfare. Indeed, many codes make that consideration 'paramount'. Among questions dealt with under this obligation are: Who are the public? (Citizens of other countries or just fellow citizens? Employees of one's own company or just 'ordinary people'?) How safe is 'safe' (see Risk)? What is the public welfare? Does treating the public health, safety or welfare as paramount mean that an engineer must sometimes blow the whistle on his employer?

The second category concerns obligations to employer or client. Engineers are supposed to be faithful agents or trustees of their employer or client. Not only should they protect trade secrets, maintain confidentiality, avoid (or, at least, reveal) conflicts of interest, make clear the limits of their expertise, and try to use resources efficiently, they should also make sure that an employer or client understands the full implications of any decision in which an engineer is involved. Where an employer or client is a large corporation, there are special problems of determining *who* must understand for the employer or client to understand.

The third category concerns obligations to other engineers. Not only should engineers not discriminate against one another or compete unfairly; they have an obligation to provide engineers under their supervision with opportunities for professional development.

The fourth category, obligations to the profession, is a miscellany of questions. Engineers have an obligation to increase the competence and prestige of the engineering profession. Are they then sometimes obliged to reveal their employer's trade secrets to the profession? Engineers have an obligation to make public statements on engineering matters only in an objective and truthful manner. How forceful can an engineer's manner become without ceasing to be objective? Do engineers have an obligation to participate in engineering societies? What is the relation of this obligation to that of faithful agent and trustee of the employer or client?

Enlightenment, Continental

The Enlightenment is frequently portrayed as a campaign on behalf of freedom and reason as against dogmatic faith and its sectarian and barbarous consequences in the history of Western civilization. Many commentators who subscribe to this view find the Enlightenment's cosmopolitan opposition to priestly theology to be dangerously intolerant itself, too committed to uniform ideals of individual self-reliance without regard to community or diversity, or to recasting human nature in the light of science. Modern debates about the nature of the Enlightenment have their roots in eighteenth-century controversies about the arts and sciences and about ideas of progress and reason and the political consequences of promoting them. Even when they shared common objectives, eighteenth-century philosophers were seldom in agreement on substantive issues in epistemology or politics. If they were united at all, it was by virtue only of their collective scepticism in rejecting the universalist pretensions of uncritical theology and in expressing humanitarian revulsion at crimes committed in the name of sacred truth.

1 Modern assessments

The eighteenth-century Enlightenment is the only period of modern history described, most often by its detractors but sometimes also by its admirers, as a single intellectual movement or campaign, orchestrated around a common set of themes. Its leading thinkers, comprising Europe's first intelligentsia, are perceived as jointly committed to liberating mankind from the tyrannies of dead dogma and blind faith. They held that the barbarism of European culture in its Dark Ages had been due to ignorance and bigotry, and that the Crusades, the Inquisition and sectarian wars had been responsible for retarding the moral development of individuals and fragmenting their political communities. Unlike earlier philosophers who had sought to interpret the world, the advocates of Enlightenment were determined to change it. Their frequent engagement in public policy or status as civil servants and advisors to princes, their esteem for science over tradition, their empiricism and apparent preference for applied philosophy over metaphysics, have made them seem wedded to a belief in the unity of theory and practice. These same features of their doctrines or professions have in turn inspired the opposition of critics who, like Edmund Burke among their contemporaries, judged Enlightenment philosophy responsible for the French Revolutionary overthrow of the *ancien régime*, or who, like Alasdair MacIntyre today, blame it for inaugurating the monolithic philosophical trappings of modernity. Such charges against a so-called 'Enlightenment Project' have figured centrally in hostile interpretations of its significance over the past 200 years. On the one hand, both its conservative and liberal critics, such as Hegel at the turn of the nineteenth century or Jacob Talmon in the mid-twentieth century, have condemned its universalist philosophy of the rights of man, which they see as having been unsheathed in the Jacobin Terror and subsequently in the totalitarian regimes of our own day, whose vast schemes of social engineering are said to be inspired by its supposition that human nature may be recast like pliant clay. On the other hand, communitarian and postmodernist opponents of the Enlightenment, such as Charles Taylor in the first instance and Michel Foucault in the second, have equally decried its moral atomism and superficial understanding of the self, or alternatively its espousal of uniformitarian doctrines which leave scant room for individual diversity or cultural pluralism (see Community and communitarianism; Postmodernism). Most hostile of all are those commentators who have followed the contention of Max Horkheimer and Theodor Adorno that the Enlightenment's purely instrumental grasp of scientific rationality paved the way to the organization of genocide in the Second World War.

Much of the criticism of the Enlightenment Project has been concentrated upon two of its most seminal figures - Adam Smith and Immanuel Kant - the first because his liberal philosophy appears to remove all notions of absolute value from interpersonal relations, the second because his account of moral duty and autonomy seems to disregard the complex motives which actually inspire human action. In his attachment to universal rules legislated in the light of abstract reason; in his insistence (in modern parlance) upon preferring the right over the good; in his impartiality and essentially cosmopolitan indifference to difference, Kant in particular has come to be regarded as the principal spokesman for the vacuous subjectivism and empty formalism of the whole Enlightenment Project. The philosophical hermeneutics of Hans-Georg Gadamer takes up a fundamentally Hegelian position in criticizing Kant's, and therefore the Enlightenment's, abstract notion of individual self-awareness on account of its deracination from real experience. But Jürgen Habermas, in reaffirming the critical stance of Kant's philosophy, equally upholds the emancipatory aims of that same Enlightenment in its subjection of traditional beliefs to the

scrutiny of reason, which cannot but undermine tradition's authority.

Among modern social philosophers, Habermas is particularly well-disposed to what he takes to be mainstream Enlightenment thought, but the *Oxford English Dictionary* suggests an anti-Enlightenment bias within the English language itself, in identifying much the same perspective which Habermas applauds as 'superficial intellectualism' marked by 'insufficient respect for authority and tradition', adding that a *philosophe* - in the French language associated above all with the Enlightenment - is 'one who philosophizes erroneously'. Among eighteenth-century figures, only Hume and Kant, and occasionally Berkeley or Condillac, have been acknowledged by historians of philosophy as genuinely first-rate thinkers. The contributions of Hume and Kant to modern empiricism and rationalism, respectively, have nevertheless been considerable. When MacIntyre takes issue with Alfred Ayer and Richard Hare, he challenges contemporary Oxford exponents of two perspectives of an Enlightenment Project which he claims was bound to fail. The liberal principles of John Rawls' influential *Theory of Justice* (1971) also spring above all from the moral philosophy of Kant (see Rawls, J.).

2 Appraisals in the eighteenth century

Debates of the nineteenth and twentieth century about the Enlightenment's significance in European intellectual history take up themes already pursued in the eighteenth century by both its protagonists and critics, particularly in France in the 1750s in connection with the *Encyclopédie* of Diderot and D'Alembert (1751-72) and in Prussia in the 1780s and 1790s with regard to the limits of reason and the political implications of promoting its use. More than any other work of the eighteenth century the *Encyclopédie* may be regarded as the centrepiece of the Enlightenment, representing the self-image of an age of reason and invention much like the Crystal Palace would exhibit the character of an age of science and industry a century later. Assembled by contributors who formed an international republic of letters or party of humanity, the *Encyclopédie* was conceived as a reasoned dictionary of the arts and sciences, a modern monument to a classical ideal, inherited above all from Plato, that the promotion of knowledge and the pursuit of virtue should go hand in hand (see Encyclopedists, eighteenth-century).

In his preliminary discourse published in its first volume in 1751, D'Alembert, with Diderot the *Encyclopédie*'s joint overall editor, delivered what has sometimes been described as the manifesto of the Enlightenment as a whole. Taking stock of the achievements of the human mind through works of individual genius, D'Alembert lavished praise upon his precursors, including Bacon, Descartes and Leibniz among the philosophical and scientific giants of the seventeenth century. But no previous age had made such great progress along the path of knowledge as his own, he argued, in part because men of genius had turned their attention to the liberal and mechanical arts with the same enthusiasm as others had embraced pure science, in part because the human mind's productions had come to form a veritable library of useful information for a world in which prejudice could be overcome through reading. The *Encyclopédie* was an agent of general enlightenment, he thought, because it was accessible to a literate audience, transmitted in a vulgar rather than arcane language.

Some of these notions were borrowed from Fontenelle and other progressively-minded contributors to the early eighteenth-century *Querelle des anciens et des modernes*, and Diderot was to develop them further in his own article, 'encyclopédie', which appeared in volume five, of comparable length to D'Alembert's discourse, and equally designed to pay tribute to human industry and scientific inventiveness, which pushed back the frontiers of knowledge and thereby roused mankind from the dogmatic slumbers of its fundamentalist faiths. Such principles articulated one of the most central doctrines of French *philosophes* in particular, who like their patron saint, Voltaire, warmed to the achievements of English science, civility and toleration, which they characteristically took to be more robust guides to enlightenment than the predominantly classical, more archaic, forms of French culture and taste.

They were to figure as well as in the celebrations of the progress of the human mind produced by Turgot around the same time as D'Alembert's discourse, and above all, in the course of the French Revolution by Condorcet, D'Alembert's successor as permanent secretary of the French Académie des Sciences. Condorcet's sketch of the nine historical epochs through which civilization has passed, and of the tenth epoch to come, is particularly notable for its anticlericalism, its devotion to science, its faith in the power of reason to bring about societal change, and its optimistic tone adopted at the darkest moment of the French Revolution. For the past 200 years it has been regarded as the most characteristic expression of the idea of progress in Enlightenment thought, turning D'Alembert's focus upon books and treatises to more political ends and wider social objectives.

Just before D'Alembert's preliminary discourse was published, another work appeared, however, which he cites because it pursues an altogether different line of argument about the connection between virtue and knowledge. This was Rousseau's *Discourse on the Arts and Sciences* (1750), in which he contends that the trappings of civilization are but garlands of flowers around the iron chains by which mankind is weighed down (see Rousseau, J.-J.). The philosopher of nature as opposed to culture thus launched the first of his many attacks upon his own age of enlightenment. Although neither Nietzsche nor Foucault would ever recognize a debt to Rousseau in their own conjunctions of *savoir* with *pouvoir*, their critiques of the Enlightenment followed a path already mapped by him, which challenged the main thrust of the *Encyclopédie* at the moment of its birth.

The German debate on the meaning of enlightenment was launched more than thirty years later, by way of an article by the theologian Johann Friedrich Zöllner which appeared in the *Berlinische Monatsschrift* in December 1783. To the question he put, 'What is enlightenment?', numerous replies were submitted by correspondents in the course of the next several years, some published in other journals. The most important of these were by Moses Mendelssohn, who was one of Rousseau's German translators, and by Immanuel Kant. Mendelssohn sought to meet the objections to enlightenment posed by those most anxious to protect human society from overwrought change, and he argued that the discretion of each individual was a better censor of dangerous ideas than the full force of the law. To keep the inventiveness of enterprising persons in check on account of the hazards they raised was to legislate against human progress, which was a matter not for man but for Providence, he maintained, admitting that there were nevertheless certain truths useful to individuals but harmful to citizens.

In his short essay 'Was ist Aufklärung?', which appeared in the *Berlinische Monatsschrift* in December 1784, Kant introduced a similar distinction between the individual and the citizen, claiming that enlightenment was more difficult to achieve in the private than in the public domain, because of each person's ingrained immaturity or lack of courage to rely upon their own understanding. It was in the public sphere, however, rather than in private that it was most imperative for enlightenment to be gained, he insisted, and what was needed above all for its triumph was freedom. The century of Frederick the Great was not yet an enlightened age, but it was, Kant remarked, an age of enlightenment in which the obstacles to mankind's self-reliance and self-guidance were being gradually lifted. Over a decade later, he was to draw a still more optimistic portrait of the disinterested sympathy which would be felt by all mankind as it sought to live under republican constitutions which could have no interest in wars. In his essay *The Contest of the Faculties* (1798) he argued, in prophetic voice, that the human race was continually improving and that even apparent reversals like the Jacobin Terror would not arrest its further moral progress.

3 Its diversity and contrasts

Such differences of emphasis betwen French and German asessments of the Enlightenment lend warrant to the proposition, most often put forward by historians against philosophers, that any notion of a coherent and collective 'Enlightenment Project' is little more than a myth. French *philosophes*, Scottish moralists and German pietists, even when they managed to agree amongst themselves, were not committed to the same cause, it is suggested - French thinkers in particular proving characteristically more radical than their counterparts elsewhere, not least because, for the most part writers without university appointments or official duties as state servants, they were more free to speak their minds. The undeniable truth of that contention points towards greater specificity in identifying Enlightenment philosophies without obscuring the genuinely collective enterprise in which their authors were often engaged.

Thanks to a variety of moral weeklies, literary periodicals and eventually newspapers, and to an international book trade, both authorized and clandestine, philosophical essays, discourses, treatises and encyclopedias circulated on a scale unprecedented in human history and at a speed which enabled Scottish writings indebted to Montesquieu and German commentaries on those same works to cross-fertilize one another in appearing within a matter of months, as if electronically linked to the Internet today. Political thinkers of the Enlightenment served as ministers in the courts of Maria Theresa, Joseph II, Leopold II, George III, Gustav III, Frederik VI, and Louis XVI, while kings corresponded with philosophers, sought their company and solicited their advice. Literacy made the spread of enlightenment possible, granting to experts in all subjects a political presence and power in society they had not earlier enjoyed. This command of publicity by the friends of the Enlightenment makes the notion of their collective project credible, even allowing for the diverse and sometimes conflicting objectives of its adherents.

It is nevertheless imperative that due weight be placed on the substantive differences between those objectives, however much they were pursued in concert. Condillac, the most influential of the French empiricists of the Enlightenment, came to revise his own views substantially in the course of his intellectual career, attempting at first to correct Locke's epistemology by way of refining the doctrine of the association of ideas so as to explain the generation of self-awareness without recourse to intuition, while later, in his account of the statue-man, putting forward a more physiological notion of psychic life as rooted in the senses, particularly the sense of touch. The French materialists, in turn - principally Maupertuis, La Mettrie and d'Holbach - put forward a number of claims about the physical determination of morality which were similar to those of the later Condillac, although their works were received differently and came to be regarded, especially by the Church, as the most incendiary of the philosophies of the Enlightenment on account of their denial of the existence of an immaterial and immortal soul (see La Mettrie, J.O. de).

When political thinkers of the Enlightenment agreed that their aim should be to devise a set of rules for the proper management of human affairs in the light of the known tendencies of human nature, they were sometimes drawn to utilitarianism in the manner of Hutcheson, Helvétius, Beccaria or Bentham, who advocated policies which promoted the greatest happiness or least pain of the greatest number, by way of constitutional reforms which abolished physical torture and all civil retribution for moral crimes (see Utilitarianism). But from much the same premises other philosophers advocated instead sumptuary laws in order to promote economic equality and the collective ownership of property such as were proposed by Dom Deschamps, Morelly and Mably, while still others adopted the wholly contrary stance of Turgot, Antonio Genovesi and Giuseppe Palmieri, who perceived the social benefits of economic inequality and held that the state could best promote economic development by exercising as little control as possible over the liberties and initiative of its citizens.

In criticizing monolithic notions of a science of the human mind, perceived as subject to the laws of nature in a universe which it reflects, critics of the Enlightenment Project often overlook the richness and diversity of its various themes. No major thinker of the eighteenth century was more persuaded of physicalist explanations of social behaviour and culture than Montesquieu, who plainly fits the description offered by Richard Rorty, for instance, of a philosopher convinced that objective knowledge of all things, including human conduct, is possible and that mind is a mirror of nature. Yet from the single dimension of his belief in the scientific study of both matter and mind, there springs no universalism or cosmopolitanism of any kind, since above virtually all his contempories Montesquieu was specially sensitive to local variety, specificity and the uniqueness of social institutions, customs and mores.

Enlightenment philosophers - empiricists and rationalists together - are perhaps best described as sceptics who collectively framed fundamentally liberal objections to what they took to be the universalist bigotry of sacred truth. If their principal battlecry was Voltaire's 'Écrasez l'infâme', they were, on account of their commitment to toleration, drawn by an ideal of peaceable assembly such as Voltaire himself in his *Philosophical Letters* (1734) had found among the traders of the London Stock Exchange, where no church was supreme and individuals of different faiths could deal with one another as if they were of the same religion (see Voltaire). In opposing the ethnic cleansers of their day, the philosophers of the Enlightenment contributed to our understanding of what we now call crimes against humanity.

Enlightenment, Jewish

The eighteenth century in Europe saw the beginnings of Jewish emancipation, and this led to an intellectual development which came to be known as the Jewish Enlightenment or Haskalah. This movement emphasized the rational individual, the notion of natural law, natural religion and toleration, and natural rights. The effect of this form of thought was to provide a justification for the equality of the Jews with other citizens of national entities. The most important exponent of this movement was Moses Mendelssohn, who dominated the debate on the role Jews should play in the state and the rationality of Judaism as a religion. Ultimately the Jewish Enlightenment moved east and became connected with such movements as Zionism. In Germany it led to the development of the Reform movement. The Jewish Enlightenment very much set the agenda for the next two centuries of debate about Jewish ideas by seeking to analyse the links between religion and reason in Judaism.

1 Haskalah and philosophy

Haskalah (Jewish Enlightenment) is the name given to a series of movements at times resembling and often modelled on the various Enlightenment movements in western and central Europe. The Haskalah first took root in the major Prussian cities of Berlin and Königsberg in the latter half of the eighteenth century. It spread to other German cities and to Vienna; and from there, throughout the nineteenth century, to Bohemia, Galicia, Podolia, Lithuania and the southern Ukraine, especially the city of Odessa. Although each area of Haskalah had its own unique features, the *maskilim* (the adherents of Haskalah) of Europe were all committed to the social and intellectual revitalization of the Jewish communities of Europe. Their programme included the learning of European languages and developing familiarity with European culture, including philosophy, as well as a transformation of the Jewish economic profile and educational system. While *maskilim* were often few in number the Haskalah had an important impact on Jewish culture in central and eastern Europe in the nineteenth century.

The Haskalah in Prussia produced one major philosopher: Moses Mendelssohn (1729-86). Mendelssohn became one of the most important philosophers of the German *Aufklärer*, even while he remained central to the development of Jewish thought and ideological modernization. In his *Briefe über die Empfindungen (Letters on Feeling)* (1755b) and *Philosophische Schriften (Philosophical Writings)* (1761) he redirected aesthetic discussion by insisting that judgments about beauty are independent of ethical purpose or logical criteria. In 1763 he published *Abhandlung über die Evidenz in metaphysischen Wissenschaften (Treatise on Evidence in Metaphysical Knowledge)* in which he tried to shield metaphysics from the claim that its proofs for the existence of God and morality do not attain the certainty of mathematics. His reputation as a major German philosopher was assured with the publication of his Platonic dialogue *Phädon, oder über die Unsterblichkeit der Seele (Phaedo, or on the Immortality of the Soul)* in 1767. The dialogue was a philosophical best-seller and adumbrated the quintessential Enlightenment statement of belief in the immortality of the soul. Even after the publication of Kant's critical works, Mendelssohn remained a staunch defender of the demonstrability of the existence of God, as is shown in his last work, *Morgenstunden, oder Vorlesungen über das Dasein Gottes (Morning Hours, or Lectures on the Existence of God)* (1786), a work intended, among other things, to defend Mendelssohn's friend Lessing from charges of atheism and Spinozism.

Even as he took full and active part in the European Enlightenment, Mendelssohn remained committed to the development of Jewish culture and thought, as can be seen by his numerous Hebrew works, especially his commentary on Exodus, and his book *Jerusalem, oder über religiöse Macht und Judentum (Jerusalem, or on Religious Power and Judaism)* (1783). In this work, Mendelssohn applied theories of natural right to the political status of the Jews and to European societies generally. He insisted on a clear delineation of the prerogatives of Church and state in (what ought to be) a secular society. In the second half of the book he developed a philosophy of Judaism that defended his ancestral faith against charges of immorally excluding non-Jews from salvation. He insisted that Judaism embodied a revealed legislation, rather than a revealed religion and argued that Judaism does not coerce its adherents in matters of religion any more than it excludes non-Jews from salvation.

Mendelssohn used his Bible commentary to disseminate some of his ideas regarding metaphysics and politics to a larger Jewish audience. In addition, we find in his Bible commentary a distinct contribution to the emerging field of philosophical linguistics, although this side of Mendelssohn's work remained largely unknown beyond the

Jewish community, as it was written in Hebrew. Here Mendelssohn tried to develop the notion that language was a vehicle for mediating more than one intended significance. The search for authorial intention, then, although a standard concern at the time, could not proceed simply on a philological and literal level. Texts needed to be interpreted more broadly to appreciate fully the intended significance of their words, phrases and sentences. In practice, for Mendelssohn, this meant the submission of the interpreter to the ancient interpretative traditions. The recognition of the polyvalency of meanings in a text might have led Mendelssohn to a more historically rooted view of texts and their appropriate interpretations. But he tended to rest content with the traditional subtleties of the rabbinic midrashic method (see Midrash).

Mendelssohn was the only important Jewish philosopher in German-speaking lands who remained committed to Haskalah throughout his life. But mention should be made of two other members of the Berlin Jewish community who were associated with the Haskalah movement for a time. Salomon Maimon (1753/4-1800), a Polish Jew, came to Berlin in quest of opportunities for the free pursuit of knowledge. He was associated for a time with the *maskilim* of Berlin and wrote a Hebrew work designed to reconcile scientific principles with the study of the Torah. He translated Mendelssohn’s *Morgenstunden* into Hebrew and wrote a philosophical commentary, also in Hebrew, on Maimonides’ *Guide to the Perplexed* (see Maimonides, M.). Eventually, Maimon rejected the notion that Jewish culture could be reconciled with modern philosophy and devoted the rest of his career to writing several philosophical works critical of Kant’s transcendental philosophy.

The stimulus of Kantian thought was to lead yet another, albeit far less original, philosophical voice away from Haskalah, that of Marcus Herz (1747-1803). Herz was briefly associated with the Haskalah movement, but went on to become one of Kant’s earliest disciples - he was chosen by Kant to be a respondent in the defence of his inaugural dissertation. Herz thanks Kant for helping to liberate him from a life of ‘dragging a burden of prejudices’, a reference to his Jewish cultural background. His *Betrachtungen aus der spekulativen Weltweisheit (Meditations Drawn from Speculative Wisdom)*, written in 1771, represents an early commentary on Kant’s inaugural dissertation, which, like the work of so many commentators and popularizers, shows distinct misunderstanding of the Kant’s work. Ultimately, Herz made a name for himself as an important scientist and physician. As with Maimon, the Haskalah made possible his encounter with European philosophy. But unlike Maimon, he did little to advance the cause of Jewish enlightenment.

The various other centres of Haskalah produced only one other important philosopher, Nachman Krochmal of Galicia (1785-1840). Unlike the Prussians, Krochmal advanced philosophical discussion within the Jewish community alone. Although the leading intellectual of the Haskalah in Galicia, far from the German ‘intellectual marketplace’ as he put it, he became an astute observer of the German philosophical environment. Krochmal provided one of the first Jewish responses to, and adaptations of, elements of the philosophical work of Spinoza, Kant, Herder, Schelling and Hegel. In his posthumously published *Moreh nevukhei ha-Zeman (Guide to the Perplexed of Today)* (1851), Krochmal adapted Kantian epistemological concepts to demonstrate the need to interpret religious sources with an eye to their deeper philosophical significance. He then proceeded to show that the deeper philosophical significance of traditional Jewish sources, both ancient and medieval, corresponded to the most recent discoveries of the German Idealist philosophers. Using his interpretative method, Krochmal argued that a range of traditional Jewish concepts - such as belief in a personal God who created the world and revealed a desired way of life - remained philosophically coherent, for, when properly interpreted, they were shown to be concrete representations of the abstract metaphysics of Hegel and Schelling.

Krochmal responded to the regnant philosophy of history that considered Jewish culture - among many others - to be sublated in the onward march of history, by arguing that Jewish religion, because of its apprehension of the absolute, stood outside the historical ‘laws’ that mandated the eventual cultural demise of all nations and states. Although he was an important model for aspiring Jewish intellectuals in eastern Europe, his philosophical work was of limited influence. His lasting contribution would seem to lie in his implicit exposure of the unstated and culturally biased assumptions of modern idealist philosophy. His work showed that different cultural assumptions would lead to the application of idealist concepts in a way that yielded philosophical and religious conclusions that diverged significantly from those reached by the German Idealists themselves.

2 The Haskalah and the history of philosophy

The Haskalah, not unlike the Enlightenment movements of western and central Europe, produced few original

philosophical minds (see Enlightenment, Continental). But there were many lesser lights and still more followers of their guidance in the quest for an enlightened way of life and thought. For this reason at least, the Haskalah remains an important, although largely unmined, resource for the student of the history of philosophy. The hundreds of *maskilim* throughout Europe were avid consumers of French and German philosophy. They were also eager readers of Spinoza's works as well (see Spinoza, B. de). Knowing what they read and how they understood it is vital to an understanding of the spread and impact of the modernizing trends of European thought. The earliest Prussian *maskilim* emerge at a time when Christian Wolff was one of the leading philosophers of Germany. In the works of these early *maskilim*, including Mendelssohn, one can discern Wolff's distinct influence. Similarly, the ethical writings of *maskilim* in Germany display familiarity with Enlightenment ethics. One result is a turning away from the pessimistic tone of many traditional Jewish ethical writings. The influences that we observe show that the German *maskilim* were the most acculturated, and most at home, linguistically and culturally, in the world of European philosophy.

Yet the Haskalah moved eastward just as European philosophy was undergoing a revolution reflected in the works of the post-Enlightenment Idealists, and the works of Herder as well. The derivative thinking of the Eastern *maskilim* remained rooted in Enlightenment thought even as it embraced the new idealism. This often difficult combination produced fascinating tensions, facilitated by the fact that, with the exception of Krochmal, Jewish readers in central and eastern Europe tended to read popularizations of Kant rather than Kant himself. What this meant in practice was that the eastern European Jewish writers and thinkers of the Haskalah often developed 'Kantian' ideas in ways that were quite consistent with central Enlightenment ideals - with assumptions and consequences that would have been unrecognizable to the master. Similarly, Jewish writers embraced certain Rousseauian notions regarding education and ethics (see Rousseau, J.-J.). Again, though, they tended to receive this material second-hand. Especially important as a popularizer of Kant and Rousseau was the Swiss writer, thinker and historian Heinrich Zschokke (1771-1848). The dependence on Zschokke for knowledge of Kant and Rousseau is particularly manifest among the *maskilim* of Lithuania.

In examining the *maskilim* as consumers of European thought, we find several matters especially worthy of note to the historian of philosophy. The first is that post-Kantian *maskilim* tended to find Kant's ethical thought thoroughly compelling, despite its overtly anti-Judaic component. Yet these *maskilim* separated Kant's ethics from his critical metaphysics. They had little use for the latter, and tended to reduce even Kant's ethics to the principles of duty and autonomy. They then went about showing how such ethics were compatible with the biblical *mitzvot*, despite the fact that these divine commandments might readily seem thoroughly heteronomous, and certainly seemed so to Kant. Here Kant's ethical thinking was removed from its place within his thought and enlisted on behalf of a very different, modernizing cum apologetic cultural project.

Post-Hegelian *maskilim* tended to have a very limited understanding of Hegel. Here again Krochmal is the exception. Yet thinkers who had no apparent understanding of Hegel's metaphysics, ethics or politics were drawn to his philosophy of history. Once again we find these thinkers drawing selectively from Hegel's thought. Even when some paid rhetorical lip service to the dialectical movement of history, what interested the *maskilim* most was the teleological view of history that Hegel's thought seemed to legitimate. This view in turn allowed the *maskilim* to conceptualize observed changes in Jewish history as part of a larger drama that they could interpret as pointing towards the fulfilment of their own cultural aspirations. The continued influence of Enlightenment ideals is manifest here.

Eclectic borrowing from Spinoza may be discerned in the work of some of the more religiously radical *maskilim*. They wanted to re-enact the drama of Spinoza's liberation from the Jewish religious tradition. Yet they sought to do so without adopting Spinoza's universalism.

3 The afterlife of the Haskalah

Throughout the encounter with post-Enlightenment European thought in the various centres of Haskalah, the movement in some ways remained very much modelled on the European Enlightenment. Everywhere and always committed to Enlightenment rationalism, the *maskilim* remained thoroughly optimistic regarding the ability of the Jewish community to generate a rational culture even as they expressed deep contempt for the Jewish masses, and often for its rabbinic elite. But European thought and politics moved on, and for some the efforts of the *maskilim* to graft more recent thinking onto the tree of rationalism and optimism came to appear hopelessly naïve. Many

others, like Maimon and Herz, came to see the effort to reconcile European thought - however well or poorly understood - with Judaism, traditional or reformed, as irrelevant at best, dishonest at worst. Thus, in each of its centres, the Haskalah, like the Enlightenment itself, tended to be of limited duration. Yet in its own limited way it helped bring about fundamental intellectual change in the Jewish communities of Europe. It promoted and legitimized new areas of inquiry among Jews and contributed mightily to the emergence of new philosophical and political ideologies as Jews entered the twentieth century.

Enlightenment, Russian

When Russia embraced secular European ways of thought under Peter the Great, its educated elite came into contact first with the German Enlightenment, which combined the rationalism of Descartes and Leibniz with the emotionalism of Protestant pietism. With its acknowledgement of established authority, and emphasis on a person's responsibility to the community rather than individual rights, this strand of early Enlightenment thought suited the state-building of Peter.

By the second half of the eighteenth century, the universality of the French language, the influence of geniuses such as Montesquieu and Voltaire, and the formation of a conscious Enlightenment party among the French philosophes *meant that their polemical writings carried the mainstream of progressive thought. It was this Enlightenment that was embraced by Catherine the Great, who professed its tenets: tolerance and the conviction that perfecting social organization would ensure human happiness. She encouraged the growth of an intellectual elite to spread the ideas of the* philosophes *and form an enlightened public opinion.*

Russia's tradition of absolutism and the institution of serfdom, however, proved inimical to Enlightenment values. Nevertheless, the Russian Enlightenment engendered an elite of individuals eager to act as critics and moral leaders of their society who would determine the future course of Russian social thought.

1 State Enlightenment

The ground was prepared for the Russian Enlightenment when Peter the Great reshaped Muscovy, with its Orthodox religious culture, into a modern, secular European state. In order to achieve his reforms, the Russian service elite were obliged to immerse themselves in the contemporary currents of European thought, science, social progress and literature. Some were sent abroad for training, but most learned from the technicians and educators imported from the West to modernize the state. The majority came from Germany and brought with them the philosophical outlook of their homeland. This outlook, forged in the West's recent scientific revolution, also underpinned the modern technology imported by these specialists. Consequently, Petrine Russia sought advice on education from Leibniz and Christian Wolff, and it was their pupils who were recruited for the new Academy of Sciences: G.F. Müller, Schlözer and Stählin, the historians; Euler, the mathematician; and Pallas, the biologist, geographer, linguist and explorer - these were the leading scholars and scientists in eighteenth-century Russia.

The intellectual framework which these teachers brought with them was constructed from the rationalism of Descartes and the natural-law ideas of Leibniz and Pufendorf. The rationalism and legalism were imbued, however, with the emotionalism of Protestant pietism, whose proponent was Christian Wolff. Both the pietist emphasis on the acceptance of properly constituted authority, whether religious or political, and its stress on a person's obligation to serve the community rather than on selfish individual rights, suited the requirements for state-building initiated by Peter. The influence of this particular German strand of Enlightenment was reinforced by the prestige of the eighteenth-century polymath M.V. Lomonosov (1711-65) whose work and writings reflected the scientific education he had received in the universities of Marburg and Freiburg, with their strong pietist tradition. A constant promoter of the 'common good', he was instrumental in the founding in 1755 of Moscow University, where the employment of a number of influential German professors ensured the persistence of the German outlook.

Despite the influx of Western patterns of thought the essence of Enlightenment - and accumulation of knowledge permitting the critical appraisal of social relationships in order to improve human life - was not assimilated by Russia in the first half of the eighteenth century. It was in fact negated when Peter exploited the means of Enlightenment as an instrument to transform society from above in order to augment the state's military, economic and administrative efficiency. Nevertheless, some of the prerequisites for Enlightenment, such as the founding of scientific, educational and publishing institutions, had been established. And crucially, a secular conceptual framework had been created outside traditional Orthodoxy.

2 Enlightenment of society

The mainstream of the European Enlightenment, represented by the works of the French *philosophes*, penetrated

into Russia from the 1740s, but the progress and development of the Enlightenment in Russia is intimately connected with the person and the reign (1762-96) of Catherine the Great, who declared her allegiance to the ideals and aims of the Enlightenment in her memoirs. In 1767 she published her *Nakaz*, or the *Instruction* provided to guide the deliberations of the deputies summoned to a Legislative Commission. Although the rational precepts of Bielfeld and Justi and the pietist morality of Christian Wolff are present in the document as reminders of the German influence, the *Instruction* was mainly composed of liberal ideas taken from the *Encyclopédie*, from Beccaria's *Dei delitti e delle pene* (*On Crimes and Punishments*) (1764) and above all from Montesquieu, whose *De l'esprit des lois* (*The Spirit of the Laws*) (1748) was called by Catherine her 'prayer book'. The *Instruction* demonstrated the sovereign's respect for Enlightenment thought and gave it imperial sanction.

Another Enlightenment initiative of Catherine's was the 1766 essay competition on the peasant question organized by the Free Economic Society, Russia's first independent cultural institution, and inspired by the economic arguments of the *Encyclopédie* and the physiocrats. Few Russians competed, but among the 164 entries were essays by Voltaire and Marmontel.

The Free Economic Society competition and the *Instruction* linked Russia with the wider European Enlightenment in two ways. First, it provided Europe with another example of an 'enlightened despot' in the person of Catherine. It was important in the eyes of the *philosophes* that sovereigns themselves should understand the lack of justice in the existing social order. In Catherine the Great the French *philosophes* discovered an empress prepared to play the part of an 'enlightened monarch', eager to buy their books, to correspond with them, to invite them to visit her, to give them patronage and even to carry out the reformation of society they proposed. Proof of this was her declaration of admiration for Montesquieu in a letter to d'Alembert where she explained that she had plagiarized him 'for the good of twenty million people, which must come of it'.

Second, the consultative assembly called to consider the *Instruction* was an example of the involvement of broader sections of society in the Enlightenment. It supplied a precondition for the spread of the Enlightenment: the establishment of public forums for debate and publicity, permitting individuals to participate in the process of social reform. One of the striking propositions in the *Instruction* (article 58) was the need 'to prepare the Minds of People' before the implementation of improved legislation.

European Enlightenment was no longer exploited merely as an instrument to strengthen the efficiency of the state; the welfare of society and that of its members was now the objective. 'The happiness of one and all' was the motto on the medal given to the deputies summoned to respond to the *Instruction*, and one of its closing articles (521) stated that its propositions were 'the Choice of those Means, whereby the Russians may be rendered the most happy possible of Mankind'.

3 Means of Enlightenment

After the suspension of the Legislative Commission, as a result of the outbreak of the Turkish War, other channels were found for the diffusion of Enlightenment thought. In 1768 Catherine founded a 'Society for the Translation of Foreign Books' which by 1772 had published over forty titles, including extracts from the *Encyclopédie*, Montesquieu and Voltaire. Meanwhile she had called into being the publication of moral weeklies, modelled on the *Spectator* of Addison and Steele, that popularized Enlightenment attitudes. She opened state archives to aid private historiographical enterprises. Licensing requirements for presses and publishing houses were abolished in 1783. In Catherine's approval for private charitable initiatives in popular education, and particularly for Ivan Betskoi's plans for foundling homes that would produce a new type of citizen, support was given to the institutionalization of the social vision of the Enlightenment.

Although these means were all under imperial tutelage, there seems to have been a policy of encouraging a class of intellectuals who would guide society, correct its defects and help eradicate the obstacles frustrating the creation of an enlightened society. Eventually, with the emergence of a social elite that was not an official part of state authority, public opinion began to take on a corrective function and became a power factor with which the state had to contend.

In this a leading role was played by writers, aware of themselves as forming a 'republic of letters', as Mikhail Kheraskov, Director of Moscow University's Press and Library, called the group of young men who had gathered around him. No original contribution, however, was made by them to European Enlightenment philosophy. For

these Russian writers, Enlightenment meant initially the reception and later the adaptation of Western developments, and the participation of Russia in the general cultural development of Europe. Their own function was that of the mediator, spreading the ideas of the French *philosophes* of the previous generation. This insinuation of Enlightenment ideas into the consciousness of Europeanized Russians was as essential a part of the Enlightenment as the composition of the key works had been.

The most prominent director of this process was Nikolai Novikov (l714-1818), originally a minute-taker at the Legislative Commission where he would have noted the shaping of a rudimentary public opinion. Following the Commission's disbandment, Novikov appealed to that newly aware public as editor of a series of moral weeklies which castigated obscurantism and promoted the image of the truly enlightened citizen. The 1770s saw Novikov making a significant contribution to the development of publishing, and in 1779 he obtained the lease of Moscow University Press, which dominated Russian publishing for the next decade. Simultaneously he created the Typographical Company, a significant independent publishing concern.

Novikov was also a leading figure in Russian Freemasonry, one of the principal channels for the dissemination of Enlightenment values. In the 1770s the outlook of the Russian Freemason was broadly that of the approved *philosophes* and for Russians at that time the terms 'Voltairean' and 'Freemasonic' were synonymous. But later, Russian Freemasonry, under the influence of pietism, shunned the radical trends of the *philosophes* and nurtured a moderate Enlightenment which refused to become anti-Christian.

The fusion of Enlightenment values with a heightened moral awareness and religious and spiritual sympathies could prove a powerful amalgam. This was shown by another significant figure of the Russian Enlightenment, Aleksandr Radishchev (1748-1802). Radishchev studied at Leipzig, a centre of pietism, where he was also influenced by the later radical generation of *philosophe* writers: Mably, Raynal, Helvetius and Rousseau, who argued that there was a need to change institutions in order for humanity to be able to realize its true potential. This combination of spiritual enthusiasm, moral commitment and a desire for institutional change, particularly for the abolition of serfdom, was crystallized in Radishchev's *Puteshestvie iz Peterburga v Moskvu* (*Journey from St Petersburg to Moscow*) (1790), the most radical statement of the Russian Enlightenment.

4 Consequences of Russian Enlightenment

For publishing his *Journey from St Petersburg to Moscow* Radishchev received a death sentence, commuted to ten years of exile. Novikov was also sentenced in 1792 to fifteen years of imprisonment for his involvement with Freemasonry. This repression signalled the end of Catherine's enthusiasm for the Enlightenment, which had been blighted by the Pugachev rebellion and the French Revolution. At the end of her reign it seemed the Enlightenment had left little trace on Russia's official institutions. However, a cultural elite among the nobility had emerged as a self-conscious civil society, steeped in Enlightenment values and yearning to be free from the shackles of the state. The Enlightenment had taught them to question Russia's traditional political structure, particularly autocracy and serfdom. The Enlightenment belief in the perfectibility of society, the pursuit of happiness, and the prospect of a rational code of laws persisted. It was a faith protested with fervour by men nurtured in the Masonic lodges which imparted a particular spiritual earnestness to the Russian Enlighteners. Here was the breeding ground for the Russian intelligentsia of the nineteenth century.

Enlightenment, Scottish

This term refers to the intellectual movement in Scotland in roughly the second half of the eighteenth century. As a movement it included many theorists - the best known of whom are David Hume, Adam Smith and Thomas Reid - who maintained both institutional and personal links with each other. It was not narrowly philosophical, although in the Common Sense School it did develop its own distinctive body of argument. Its most characteristic feature was the development of a wide-ranging social theory that included pioneering 'sociological' works by Adam Ferguson and John Millar, socio-cultural history by Henry Home (Lord Kames) and William Robertson as well as Hume's Essays (1777) and Smith's classic 'economics' text The Wealth of Nations (1776). All these works shared a commitment to 'scientific' causal explanation and sought, from the premise of the uniformity of human nature, to establish a history of social institutions in which the notion of a mode of subsistence played a key organising role. Typically of the Enlightenment as a whole this explanatory endeavour was not divorced from explicit evaluation. Though not uncritical of their own commercial society, the Scots were in no doubt as to the superiority of their own age compared to what had gone before.

1 Overview

The Scottish Enlightenment may be conveniently dated from the publication of Hume's *Treatise of Human Nature* (1739-40; see Hume, D.) to the revised sixth edition of Smith's *Theory of Moral Sentiments* (1790; see Smith, A.) It can be fairly described as a 'movement' since it was not confined to a handful of authors but encompassed upwards of fifty participants, who all either knew or were aware of each other. Unlike in France, the Enlightenment in Scotland had strong institutional and establishment roots being based in the universities and the various satellite groups and societies to which even non-academics like Hume and James Hutton or law-lords like Henry Home (Lord Kames) and James Burnett (Lord Monboddo) belonged. As a movement it was also multifaceted. Scientific theory and experiment were well represented. Some of Isaac Newton's earliest disciples were Scottish, including, notably, Colin Maclaurin. Important work was undertaken by William Cullen and Joseph Black in chemistry and at the end of the period Hutton laid the foundation for uniformitarian geology. Literary theory was also prominent with treatises on rhetoric by George Campbell (1776); and Hugh Blair (1783); disquisitions on taste by Alexander Gerard (1759), and many others, plus pioneering works of literary criticism by Thomas Blackwell (notably Blackwell 1735). In philosophy a number of Scots, led by Reid, developed their own Common Sense School, which was stimulated by Hume's perceived scepticism and was critical of the entire 'way of ideas' (see Common Sense School; Reid, T.).

2 Social theory

Perhaps the most characteristic aspect of the Scottish Enlightenment was its social theory and it is upon that aspect that this entry focuses, taking the term to include historical and moral theory.

The Scots took human sociality to be an evidentially warranted fact. A common explanation of it was that humans possessed a social instinct or appetite. This was seen as 'social' rather than simply familial, and Kames (1774), among others, undertook a detailed comparison between human and animal association. Despite some similarities, the distinctiveness of human sociality was insisted upon especially in the form of non-instrumental social ties such as friendship and loyalty. Part of the significance of this commitment to evidence was the deliberate rejection, most notably by Hume (see Hume, D. §§4-5), of the conceptions of a state of nature and a social contract.

Not only were these notions fanciful but they over-emphasized the role of purposive rationality. Here the Scots' views differed from those typical of the French Enlightenment and of English thinkers like Priestley. For these latter thinkers Lockean epistemology (see Locke, J.) had laid the foundations for an essentially optimistic 'perfectibilist' philosophy. Since to mould experience is to mould human character, then, informed by the findings of reason, it becomes possible to set humans irrevocably on the right track. Accordingly, the more rational society becomes, the more rational will be the experience that it passes on to the next generation. For the Scots this was simplistic. In practice, the scope of reason was circumscribed by habit and social convention; social norms, for example, were the product of socialization not rational insight. In the case of government this meant that although they all had their origin in violence, 'time by degrees… accustoms the nation to regard as their lawful or native princes, that family which at first they considered as usurpers' (Hume [1741-77] 1987: 474-5). Legitimacy in

practice was the work of sentiments over time rather than the correspondence (or not) to some rational principle, like consent.

This link between social experience and normative judgments was the linchpin of Smith’s *Theory of Moral Sentiments* (1757). To Smith the effects of social intercourse teach what behaviour is acceptable and in due course individuals internalise these social judgments as conscience, viewing their own actions and motives as an ’impartial well-informed spectator’ would (see Smith, A. §3). The assumptions in Smith’s moral philosophy were widely shared. Following the lead of Francis Hutcheson they sought on the one hand to dismiss ’rationalist’ accounts of morality (it was ’more properly felt than judg’d of’ (Hume 1739-40: III.1.2)) and, most especially, on the other to undermine the egocentric assimilation of ’morality’ to self-interest as in the work of Thomas Hobbes and Bernard Mandeville. Against the pretended naturalism of Hobbes and Mandeville, all the Scots insisted on a true naturalism, the facts of human nature testifying in their view to the presence of truly moral experience, a disinterested concern for the wellbeing of others. Hutcheson invoked a special ’moral sense’ (as did, though not identically, Kames (1751) to explain this concern, while both Hume and Smith (without being in total agreement) rejected this recourse to a direct sense, referring instead to a concurrence of sentiments by means of a principle of sympathy (see Hume, D. §3; Smith, A. §2).

This sensitivity to socialization also meant the Scots were sceptical of the supposed achievements of Great Legislators like Lycurgus in moulding social institutions. Instead the Scots drew attention to the accidental and gradual formation of these institutions; in a phrase of Adam Ferguson’s, co-opted by later critics of rationalism like, for example, Hayek (1960), ’nations stumble upon establishments which are indeed the result of human action, but not the execution of any human design’ (Ferguson 1767); see Ferguson, A.). This is an exemplification of the ’law of unintended consequences’, of which the other classic formulation in the Scottish Enlightenment was Smith’s ’invisible hand’, whereby pursuit of self-interest by individuals furthered the public interest. While this has a clear bearing on the operation of markets, it was also used more generally - by John Millar, for example (1787, volume 1), to account for the development of the jury system.

This diminution of the role of rationalistic individualism was part of the Scots’ endeavour to explain social institutions as the effects of correspondingly social causes. They sought to go beyond the mere cataloguing of facts and provision of indiscriminate historical narrative to the tracing of the chain of causes and effects (see the Preface to Kames (1758)). This was typically executed by writing ’natural histories’ (as in Hume (1757)). The key assumption was that human nature was constant and uniform in its principles and operations (see Human nature, science of in the 18th century). From that premise the theorists traced the development of key institutions, such as property, government, ranks, the status of women and religion, from simplicity to complexity or from rudeness to civilization. As a means of organizing this development, emphasis was laid, as Robertson said, on different ’modes of subsistence’ (1777: Book 4). With Smith’s account seemingly seminal, social development was seen to fall into four stages - hunting, herding, farming and exchanging (see Smith, A. §4). In outlining this development, evidence from contemporary ethnography and classical history was combined in a deliberate utilization of the comparative method. Such comparisons, as well as being a way of checking the validity of any particular report, enabled them both to sift out ’chance’ or random associations from truly causal conjunctions and to supply the missing links in the causal chain. This permitted them self-consciously to write universal histories. The title of James Dunbar’s *Essays on the History of Mankind in Rude and Cultivated Ages* (1780) captured what was typical of this general enterprise. The overall aim of these inquiries was to render the ’amazing diversity’ (as Millar termed it (1779: 3rd edition, Introduction) of social life explicable. While later philosophers like Collingwood (see Collingwood 1961) have heavily criticized this view of the past, for the Scots of the Enlightenment, history was (in Hume’s phrase) a branch of the ’science of man’. It was also openly evaluative.

3 Civilized society

The Scots regarded their own society as belonging to the fourth commercial stage. Given that ’industry, knowledge and humanity’ are indissolubly linked (see Hume (1752) 1741-77), and present in commercial societies, then, in contrast, earlier savage societies were indolent, ignorant and cruel. Commercial society was ’polished’; moral sentiments were refined; taste was delicate; religion had lost much of its superstitious overlay. These features fitted together to characterize not only their own ’civilized’ society but also their theoretical comprehension of it. In this way their social theory meshed with their moral, aesthetic and religious thought. A nation of savages would live in

small scattered groups, worship many gods, have a dull moral sense and a crude taste. But refinement in all these linked spheres develops as humans gradually succeed in triumphing over the dictatorship of needs.

What was seen especially to distinguish a civilized society was the operation of the rule of law, and this was reflected in the salience the Scots attached to justice. Hume, Smith and Kames, though differing in details, all agreed in regarding justice as indispensable to social life. What made this fourth stage 'commercial' was that within it everyone was 'in some measure a merchant' (Smith 1776: Book 1, Chapter 4). As Smith argued, the decisive ingredient of this stage was the extent of the division of labour, which, in its turn, depended on the extent of the market (see Smith, A. §4). Although bartering was a natural disposition it required the stability wrought by the rule of law to become decisively effective. Once the division of labour was established it greatly increased the material wellbeing of the inhabitants, but that it also had deleterious effects was widely recognised. Ferguson and Kames evaluated these using the long-standing vocabulary of 'corruption'. For Ferguson these effects were part of a more pervasive weakness of commercial societies. He was most especially concerned about the passivity - the preoccupation with 'private' affairs - that these societies engendered. Liberty, he believed, could not be secure if all it meant was obeying just laws; it also needed active involvement. It was to this end that he wished to see a revival of public spirit in the form of militias. Smith, like Hume, did believe that 'modern liberty' came from rule-following, since a stable framework, provided by the inflexible administration of justice, permitted individuals to pursue their own interests in their own way. He did nonetheless recognize, as an unintended consequence of the specialization attendant on the division of labour, that it affected adversely the labourer's virtues. His remedy was the provision, at the public's expense, of primary education. This mixture of analysis and judgment by the Scots in their treatment of their own society is characteristic of the Enlightenment in general and demonstrates that for all their undoubted distinctiveness there truly was a Scottish Enlightenment.

Enthusiasm

For much of the seventeenth and eighteenth centuries, enthusiasm denotes a state of (claimed) divine inspiration. The claimed inspiration is almost always seen by those who employ the term as delusory, and enthusiasm is almost always seen as bad, akin to fanaticism, irrationality, and madness. The term is most commonly applied to Protestants outside the Church of England and, at times, to Catholics and pre-Christian mystics. Throughout the period, enthusiasm much less often denotes devotion and zeal or poetic inspiration. In the nineteenth century, concern with enthusiasm declines.

There are various debates about enthusiasm, understood as claimed divine inspiration. One concerns its causes. Thomas Hobbes (1651) suspected that much enthusiasm was hypocritical, a political ploy. Others linked enthusiasm with melancholy. Henry More (1662) argued that melancholy causes both overheated passions and an overheated imagination; enthusiasts suppose that anything extraordinary, such as the state of their passions, must be due to God, and so conclude that they are inspired. Later, Isaac Taylor (1823) drops the reference to melancholy but leaves an excessive imagination, trespassing on the terrain of reason, as the etiology. Of the cases where no explanation is obvious, Meric Casaubon (1656) argues that the cause is likely still natural; there are many extraordinary yet natural events. All note that attention and admiration from others discourages critical thought about one’s claims to inspiration.

More, Casaubon and Taylor proceed by cataloging varieties of enthusiasm, treating each as a natural and medical rather than supernatural and possibly heretical phenomenon. Although they see that their approach could, in other hands, furnish a thoroughly sceptical account of religious experience, they do not intend to rule out true divine inspiration. They merely quarrel with contemporary claims to it.

Another debate concerns why enthusiasm is bad. Enthusiasm can be criticized on epistemic grounds. Enthusiasts justify their claims, not by reason or faith, but by citing direct communication from God. John Locke (1700) asks why we should believe that such communication has occurred. This cannot be proven by citing the feeling that the claim is from God, nor by noting that we cannot explain why the claim is made, nor by citing our strength of conviction, nor by showing by reason that the claim is true. One needs reason to show that the claim comes from God. Locke thinks this is possible: Moses’s doubts were dispelled by the burning but unconsumed bush and the transformation of the rod into a serpent. But Locke supposes contemporary enthusiasts have no such assurance.

Enthusiasm can be criticized on religious grounds. It leads to schisms in the Church, and an opposition to church government, since mediators between oneself and God are unnecessary. It leads one to read, or even ignore, Scripture in light of one’s own fancy, rather than in light of scholarly interpretation. Jeremy Taylor (1854) worries that enthusiasts bypass the established ways to grace. More’s attack on enthusiasm is motivated by his desire to defend Christian belief and experience as rational. Enthusiasts, by abandoning reason for an ‘inner light,’ make this impossible.

Enthusiasm can also be criticized on moral and political grounds. Enthusiasm was often seen as a leading cause of the Anabaptist Peasants’ Revolt and the English civil war. On the standard view, enthusiasts foist their views on others with force and intolerance, since they are convinced that they act in God’s name. They are rarely up for reasoned discussion with others, particularly given the private nature of their inspiration. They ignore common morality for ‘higher’ concerns. And in opposing church government, they bring anarchy, since church government is vital to civil government.

Against this, David Hume (1741) gives an idiosyncratic analysis: religions based on enthusiasm have violent beginnings, given the presumptuous character of those prone to enthusiasm. But in time, these religions become calm and innocuous, since there is little church government and ritual to support their practices. In their pride and resistance to church government, Hume argues, enthusiasts become friends to civil liberty.

A third debate centres on the best way of combating enthusiasm. Some favour state coercion. The Third Earl of Shaftesbury (1711) replies that religious enthusiasm flourishes under oppression. He favours free public debate, featuring ridicule of enthusiasts. (Swift’s *A Tale of a Tub* (1704) is the most notable example.) To defend *oneself* against enthusiasm, Shaftesbury recommends self-knowledge sufficient to identify the true causes of any supposed

inspiration. For those infected, More recommends temperance, humility, and reason. Jeremy Taylor recommends prudence.

A fourth debate centres on distinguishing good and bad enthusiasm. More, Locke and Isaac Taylor suggest various tests for true divine inspiration. In addition to public phenomena such as the burning bush, the beliefs and actions which proceed from the inspiration must be moral, reasonable and consistent with Scripture. Worries about what happens should only some of these tests be fulfilled, like worries about Biblical instances of enthusiasm that do not meet these tests, are largely ignored. The emphasis is on exposing the bad, not identifying the good.

Here Shaftesbury is an exception. He argues in favour of enthusiasm, largely because he treats any divine inspiration not as a matter of supernatural prophesying, quaking, or speaking in tongues, but as a natural raising of the imagination in the presence of beauty and goodness. Enthusiasm, he argues, is needed for any extraordinary achievement. Without it, life is dull and brutish.

In the nineteenth century, enthusiasm comes to be usually understood as mere devotion and zeal, without implying divine inspiration as their cause. The term ‘enthusiasm’ largely ceases to name an object of philosophical debate, since whether devotion and zeal are good or bad depends largely on the ends to which they are put. Debate about divine inspiration continues in literature on the epistemology of religion. But in the nineteenth century the issue becomes less pressing - perhaps because the Evangelical movement brought enthusiasm into the Church of England, perhaps because enthusiasts were seen as less of a political threat, or perhaps because increased scepticism about defending Christianity on rational grounds made the contrast between rational and enthusiastic believer less sharp.

Environmental ethics

Theories of ethics try to answer the question, 'How ought we to live?'. An environmental ethic refers to our natural surroundings in giving the answer. It may claim that all natural things and systems are of value in their own right and worthy of moral respect. A weaker position is the biocentric one, arguing that living things merit moral consideration. An ethic which restricts the possession of moral value to human persons can still be environmental. Such a view may depict the existence of certain natural values as necessary for the flourishing of present and future generations of human beings. Moral respect for animals has been discussed since the time of the pre-Socratic philosophers, while the significance to our wellbeing of the natural environment has been pondered since the time of Kant and Rousseau. The relation of the natural to the built environment, and the importance of place, is a central feature of the philosophy of Heidegger. Under the impact of increasing species loss and land clearance, the work on environmental ethics since the 1970s has focused largely on one specific aspect of the environment - nature in the wild.

1 Respect for life and the 'natural'

Living things are characterized by a tendency to preserve and maintain themselves in the face of environmental challenge. Aristotelian and Stoic thinkers regarded such self-preservation as an 'end' or *telos* at which living things aim. A weaker conception of the endeavour to maintain life is found in Spinoza's conception of *conatus* (see Spinoza, B. de§§9-11). The term 'autopoeitic' has been coined more recently to refer to those processes which are self-producing and self-maintaining. Are living things - characterized as having *telos*, *conatus*, or being autopoeitic - worth respecting for themselves (see Moral standing §§1-2)? And would such respect be moral? Only in the present century has an affirmative answer to both questions been argued in detail (see Taylor and Mathews, in Brennan (ed.) 1995; O'Neill 1993).

This contrasts with moral concern for animals, which can be traced back to the pre-Socratic philosophers of ancient Greece (see Presocratic philosophy). The Renaissance essayist Montaigne referred to them as our 'brothers and companions', while Jaques, in Shakespeare's *As You Like It*, made a striking plea for the rights of deer to graze in the forest undisturbed by hunters. A peak of concern for animals was reached in the eighteenth century when there was great debate over whether orang-utans should be classified as a kind of human. Since then, various forms of animal liberation have been proposed on both consequentialist and deontological grounds (see Consequentialism; Deontological ethics).

It was also in the eighteenth century that the Swiss philosopher Jean-Jacques Rousseau urged extending our moral concern beyond animals to include care for plants and all living things. Deploring the utilitarian preoccupation with medicinal uses of herbs, he quips: 'It is no use seeking garlands for shepherdesses among the ingredients of an enema' (1782: 110). At roughly the same time, Immanuel Kant's *Kritik der Urteilskraft* (*Critique of Judgment*) (1790) emphasized the importance of aesthetic experiences of nature to human wellbeing (see Kant. I. §12). Kant does not, however, suggest that animals or other natural things have any moral worth in their own right. If it is morally wrong to beat a dog or damage a beautiful landscape, this will be because of the damage these acts do to human sensibilities and character.

Rousseau was the inspiration for French romanticism and can claim to be the first environmental ethicist. Two centuries later, Aldo Leopold, professor of forestry at the University of Wisconsin unconsciously echoes him: 'Examine each question in terms of what is ethically and aesthetically right, as well as what is economically expedient. A thing is right when it tends to preserve the integrity, stability and beauty of the biotic community' (Leopold, in Zimmerman *et al*. (eds) 1993). Leopold's land ethic has been philosophically influential since its revival by American writers in the 1970s and 1980s.

2 Radical environmental ethics

The best-known radical ethic, Arne Naess' 'deep ecology', argues that human self-realization depends on identification with nature (see Self-realization). Deep ecology started as a doctrine of biospheric egalitarianism - that all living things have the same claim to live and flourish. It evolved into a platform meant to embrace all those who recognize the inherent value of natural things and who share a concern to preserve natural diversity whatever

their differences in underlying philosophies (see Zimmerman *et al*. (eds) 1993). A key point of deep ecology is that all living things are members of larger biotic or ecological communities. The larger community may then be regarded as a place of value, with individual needs and projects assessed in terms of their contribution to the good of the larger whole.

Other radical positions are already aligned with well-known political standpoints. Murray Bookchin's 'social ecology' is a type of Green anarchism, while some ecofeminists regard the destruction of nature as intimately linked to the oppressive structures of patriarchy (see Anarchism). Although these latter positions are associated with what Michael Zimmerman (1994) calls 'countercultural' movements, they need not be morally radical in the sense of advocating an ecocentric or biocentric ethic. Most eco-anarchists hold anthropocentric value theories, and different feminist theories give contrasting accounts of the value of nature and the position of women with respect to it. As a result, there is no generally agreed radical platform. Instead, there is often strife among competing interests. For example, deep ecology has been attacked by ecofeminists as a form of patriarchal imposition (Salleh, in Brennan (ed.) 1995) or as embodying masculine egoism (Plumwood 1993).

3 Applications and environmental politics

In an applied turn for the subject, several writers have studied the philosophy of policy and the limits of economic methods in application to environmental valuation. Typical work in this area is by Mark Sagoff, Bryan Norton and Kristin Shrader-Frechette. For the applied workers, issues about nuclear wastes, pollution, cost-benefit analysis and the working of the global economy are of central importance (see Technology and ethics). However, for many of these writers, the 'environment' in question is still the wilderness. Others, such as Henry David Thoreau and Martin Heidegger have found nature closer to home. Heidegger's work has been taken up and applied by some writers on architecture, especially Christian Norberg-Schulz (1988).

For Heidegger human life takes place 'between earth and sky' (see Norberg-Schulz 1988: 38-42). Architecture and engineering are means of bringing a landscape into being: 'The bridge gathers the earth as landscape around the stream…. It does not just connect banks that are already there. The banks emerge as banks only as the bridge crosses the stream.' The concepts of place, orientation and identification are central to his account of humans as dwelling in a land. It can also be argued that an ethic of care for the earth is derivable from Heidegger's work: the contribution of the individual to the greater totality is to protect and articulate the place they have been given to take care of. This may be the meaning of Heidegger's statement that 'mortals dwell inasmuch as they save the earth… ' (1971). This account accepts the inevitability of, and necessity for, human intervention in nature. Despite Heidegger's problematic association with German National Socialism, Norberg-Schulz provides a detoxified interpretation which permits his ideas to resonate with those of ecofeminists, Leopoldians and 'deep' ecologists.

Bertrand Russell comments in his *History of Western Philosophy* that Hitler is an outcome of Rousseau. Certainly, there are well-known connections between ecologistic thinking and the political right, not just confined to Heidegger. Ernest Haeckel,who coined the term 'ecology', was associated with the extreme right, the Hitler youth were taught to value nature and the SS training manual declared the forests of Germany to be of special value (Pois 1986). Although followers of the deep ecology platform are typically vague about the political solutions they put forward, the position has on occasion been accused of supporting 'eco-fascism'. The fear behind this accusation is that biocentrism or ecocentrism may motivate the state to be unacceptably coercive towards individuals for the sake of some larger environmental good. Usually, however, supporters of deep ecology take pains to distance themselves from fascistic or totalitarian solutions to environmental problems. It should be noted that one of the best-known published defences of environmental totalitarianism is in the work of Hans Jonas (1985), an avowed anthropocentric theorist.

4 A contested project

Since the 1970s, acceptance that living things, and possibly all natural things, have value in their own right has been the touchstone to distinguish those who are 'deeper' Green theorists from those of a 'shallower' style (see Sylvan and Bennett 1994). It very soon appeared that the animal protection movement and the 'new' environmental consciousness were on a collision course (see Animals and ethics). While animal liberationists focused on freeing animals from various human oppressions, the new ecological sensibility was less concerned about the evils of the intensive farm than with the fate of its waste stream. Extreme animal advocates thought up

schemes for reducing the total amount of animal suffering by the abolition of predation and parasitism; meantime the new ecological thinkers recognized the naturalness of suffering and death in the struggle for existence.

Behind this difference lay a lack of clarity about the concept of nature. Should humans in some sense ‘follow nature’ despite the presence of pain and harm throughout the living world (see Mill 1874; Rolston, in Brennan (ed.) 1995)? The French theorist Michel Serres (1995) diagnosed the environmental crisis as stemming in part from the inability to state coherently the distinction between ‘nature’ and ‘culture’ (see French philosophy of science §7). In a related vein, Jean-François Lyotard has suggested that animals can be wronged in a way that forbids restitution: their difference from humans means that the rules of human justice, and for the assigning of damages, cannot be applied legitimately to them. So animals are forever barred from the possibility of bearing witness according to human rules (see Lyotard, J.-F.). If Lyotard’s suggestion were extended to nonhuman objects in general, then there would arguably be no viewpoint from which a comprehensive ethic of the environment could be formulated. Notice that the grounds for such pessimism seem overstated. Even if the rules of human justice do not, literally, apply to dogs, cats and rabbits, we have no difficulty in describing actions towards animals as ‘kind’, ‘unfair’, ‘cruel’ and so on.

Maintaining a narrow perspective, the agenda set by many American, Australian and Norwegian writers was focused firmly on issues concerned with wilderness and the reasons for its preservation. Virtually no attention was paid to the built environment. Outside the cities, the environment of most people is the savannah. But it was seldom mentioned either. Instead, most environmental philosophers were concerned with the forest and the mountain, places of recreation for the elite and of permanent abode of only a few humans. Perhaps the new sub-discipline should have been called ‘the philosophy of wild places’ or ‘jungle ethics’.

Writers like Naess and Rolston have followed the eighteenth-century romantics - especially Kant and Rousseau - by emphasizing the importance of wilderness experience to the human psyche. Lifestyles in which such enthusiasms can be indulged demand a standard of living far beyond the dreams of most of the world’s population. Travel to wild places often uses the jet aircraft and motor transport. It has been argued that the motor car is at the heart of many of the most serious environmental problems, including pollution and resource depletion. The economic structures which support elite access to wilderness seem to be implicated in the destruction and pollution which provoked environmental concern in the first place. Yet there is seldom much discussion of car-dependency in the literature.

This is not the only area of silence. The exploitation, oppression and war associated with securing oil supplies and other resources are not normally discussed. A similar silence hangs over toxic waste dumping, forced movements of populations, civil war, the causes of world poverty and the other social features that have damaging environmental impact. In the absence of a discussion of the unequal use of resources and energy across different groups of people and different nations, the focus on wilderness preservation led to a suspicion that Western-style radical environmentalism had a bias against the developing countries. Perhaps, indeed, it was another aspect of the imperialist or colonizing projects of the rich countries (as suggested in Guha, in Brennan (ed.) 1995) (see Development ethics).

The project of environmental ethics involves intense scrutiny of the foundations of value theory. As a result, there is the potential for engagement with mainstream moral philosophy as well as with rational actor theory and economics. Questions about the aesthetics of nature resonate with many topics in literary and art theory, including the significance of originals as opposed to fakes (see Elliot, in Elliot (ed.) 1995). Finally, the project provides a route into discussions of the general predicaments of modernity and postmodernism, as evidenced by Zimmerman (1994) and Serres (1995) (see Postmodernism).

Epicharmus (*c*. early 5th century BC)

One of the earliest Greek dramatists, Epicharmus wrote mostly comedies with mythological content in Sicily around 500 BC. A number of philosophical passages were attributed to him in antiquity; their authenticity, sometimes doubted even then, has remained controversial, but the quotations were widely influential and remain of interest.

Although Epicharmus' comedies are lost, fragments provide tantalizing hints of their character: short farces filled with slapstick, stock characters, lively language and sententious maxims; mythological burlesques, often involving Hercules and Odysseus. His appreciation for the comic possibilities of all aspects of contemporary Greek culture led him on occasion to introduce and parody such recent developments as rhetorical theory and philosophical speculation; for example, Aristotle reports that he attacked Xenophanes, and one of his mythological plays was entitled *Logos and Logina ('Mr and Mrs Reason')*.

In later antiquity, Epicharmus' frequent aphorisms and occasional (pseudo-) philosophical passages encouraged the popular view that he was a Pythagorean sage. Treatises on physics and medicine were attributed to him and 'authenticated' by acrostics, and collections of useful but largely spurious maxims circulated under his name (one introduction to such a collection survives on a papyrus); as early as the fourth century BC the Aristotelian Aristoxenus recognized that at least one philosophical work attributed to Epicharmus was not genuine. Doubters remained a minority however.

Also in the fourth century BC, the Sicilian author Alcimus accused Plato of having plagiarized the theories of Epicharmus (whom Plato twice cites with respect); four passages cited as evidence by Alcimus and said by him to derive from Epicharmus are transmitted by Diogenes Laertius. Only the first one (fr. 1) seems likely to be by Epicharmus. Its high-flown, seemingly serious contrast between the constant mutability of human beings and the eternal changelessness of the gods in fact probably served to make a ludicrous comic point: yesterday's borrower owes no money today, and the guest invited yesterday may be refused entrance today, since in the meantime each has become a different person; a man who promised payment yesterday but refuses payment on these grounds today can be beaten by his creditor with impunity - the defaulter's complaint can be refuted on these very same grounds. On the basis of this passage, Epicharmus was later said to have invented the so-called 'growing argument': if growth is the addition of new matter, whoever grows is constantly becoming a different individual, in which case there is no enduring individual who can be said to have grown (see Stoicism §6).

The other fragments distinguish the Good in itself from good people, who show by their actions that they have learned what it is, attribute wisdom to animals, and assert that beauty is in the eye of the beholder. It is unlikely that Epicharmus is the author, and they are certainly not the source of Plato's doctrines; but they do provide fascinating evidence of the degree to which philosophical discourse could find a place on the comic stage.

Epictetus (AD *c*.50-*c*.120)

*Epictetus was a Greek Stoic philosopher of the late first and early second centuries AD. He developed Stoic ideas of responsibility into a doctrine of autonomy and inner freedom based on his concept of moral personality (*prohairesis*). Ethics and practical moral training are central to his thought, but he was also responsible for innovations in epistemology. He emphasized the need to achieve freedom from the passions and to maintain equanimity in the face of a world determined by a providential, though often inscrutable, fate. He frequently treats the Stoic Zeus as a personal deity, and his distinctive combination of personal piety and stringent rationalism (together with his pungent style) have contributed to his enduring influence.*

1 Life and works

Born in Hierapolis of Phrygia, Epictetus was a slave owned by a powerful freedman at the court of Nero. He became a follower of the Stoic Musonius Rufus and a philosopher in his own right. At around the age of 40 he was banished and moved to Nicopolis on the Adriatic coast of Greece; there he taught until his death some time after 120. His thought owed most to early Stoicism, especially its third head Chrysippus, on whom he lectured. Epictetus wrote nothing for publication, but his student Arrian (a Roman aristocrat) recorded and published his informal lectures, mostly on ethics (the *Discourses*, of which four books survive). Epictetus' formal teaching consisted of the exegesis of early Stoic texts and possibly those of other philosophers. Arrian also compiled a *Handbook* of Epictetus' teaching (the *Enchiridion*). The Neoplatonic commentator Simplicius wrote a commentary on it, and it has been widely read since its revival in the Renaissance.

2 Teachings

The central idea of Epictetus' moral teaching is the distinction between what is in our power (*eph' hēmin*) and what is not. This contrast goes back to early Stoic discussions of determinism and moral responsibility (see Stoicism §21). For Epictetus, only our mental life (thoughts, beliefs, decisions, emotions) is in our power and so 'free'; hence it and the moral state dependent on it (virtue or vice) are the key to happiness. Everything else, including bodily pleasure and pain, is subject to control by external forces and so irrelevant to genuine moral welfare.

Epictetus did not organize his teaching around the traditional triad of logic, physics and ethics. Rather (*Discourses* III 2) he developed a scheme of three topics or areas of practice. First, desires and aversions must be managed, so as never to desire the unattainable nor to flee the inevitable. Two mental techniques are recommended to achieve this: the rational anticipation of possible negative outcomes and 'reservation' (*hupexairesis*, a restriction of desires with the proviso 'if that is what Zeus wills for me'). Since the only truly valuable things are in our power, this goal can be achieved by learning the difference between what is good and what is merely 'preferred'. Second, one must learn to manage impulses and choices and learn what the appropriate thing to do is in different circumstances; one must also learn the importance of living in an orderly, well-thought-out manner. The third topic aims at gaining control over one's own assent so that all error and precipitancy are avoided.

The first topic will free us from irrational passions (*pathē*). The second will guide us in our dealings with others. The third topic - based essentially on logic and epistemology - is reserved for those who have progressed through the first two. The intellectual strength it yields should be put to use in supporting a moral life, not indulged in for its own sake - a conception of the purpose of logic which goes back to the earliest generations of the Stoic school. In the *Discourses* Epictetus stresses that logic is of no value in its own right, but that it must serve ethical needs. (He makes the same point about virtually every form of learning, whether the expertise of professional literary critics and grammarians or even his own ability to expound the classical texts of early Stoicism.) The role of logic, then, is to help us understand the workings of the world and our place in it - which requires the ability to make reliable inferences from careful observations.

Epictetus made one important innovation, which concerns the so-called 'preconceptions' (*prolēpseis*), the antecedent notions which most humans share. Earlier Stoics too were committed to the task of examining them and rendering them consistent with each other, with their experience, and with the common conceptions of other people. But for earlier Stoics the origin of these preconceptions lay in the normal experience of the world which

virtually everyone shares. Epictetus converts these preconceptions into something approaching innate ideas. The impact of this change on ethics was negligible, but it foreshadowed important epistemological developments and the openness to Platonism which one senses in Marcus Aurelius.

We may form an impression of Epictetus' competence in logic and dialectic from his account of the master argument of Diodorus Cronus §5, which shows first-hand familiarity with several different Stoic views as well as with Diodorus, and from his many references to the technicalities of Stoic logic (*Discourses* II 19).

Physics, the second traditional branch of philosophy, is largely taken over from earlier Stoic theory. The key point is the providential organization of the world by nature (which Epictetus often regards as a personal god, Zeus). Nature is a rational organizing force and the principles which guide it are similar in kind to our own rationality. Hence, like earlier Stoics, Epictetus regards it as the perfection of our own rationality to accommodate ourselves willingly to the inevitable operations of the world. Where Chrysippus had spoken of the goal of life as learning to live in accordance with an understanding of what happens by nature, Epictetus speaks more often of following the will of Zeus. This more religious tone may be due to the nature of the *Discourses*, addressed as they were to a non-specialist audience; there is no reason to believe that Epictetus' views on the importance of physics or theology to ethics differed much from those of Chrysippus or Cleanthes (whose *Hymn to Zeus* he quotes at the end of the *Enchiridion* alongside Plato's *Crito* and *Apology*, and Euripides).

3 Ethics

Ethics is clearly the core of Epictetus' teaching. Following a trend which is also apparent in the work of Seneca and Musonius, and which culminates perhaps in the *Meditations* of Marcus Aurelius, Epictetus emphasizes the importance of inner mental life. All philosophers who claimed Socrates as their basic inspiration held that happiness (Eudaimonia) was the goal of life and that it depended on the care of the soul. But later Stoics put more emphasis on the autonomy of our inner life, its independence of the contingencies of our bodily and social experience. Several features of Epictetus' thought flow from this:

(1) The contrast between what is in our power (*eph' hēmin*) and what is not: 'In our power are belief, impulse to action, desire, aversion - in a word, everything that *we* do; not in our power are our body, possessions, reputation, political office - in a word, everything that is not our own doing' (*Enchiridion* 1.1).
(2) The focus on *prohairesis*, or moral personality. Earlier Stoics seldom mention this term (which is important for Aristotle (§20), though in a different sense); Epictetus adopted it to express the idea that their moral identity is something which rational agents can control and for which they are wholly responsible. In this respect it recalls Seneca's novel emphasis on will (Latin *voluntas*). Epictetus does not refer to anything which could not be expressed by referring to the commanding faculty (*hēgemonikon)* and to assent as earlier Stoics did, but the new term permits an emphasis on inner mental life.
(3) The polarization between our impressions (*phantasiai*) and the critical use which we make of them. Impressions can be external, such as the appearance of a possible source of pleasure or pain, or internal, such as our own opinions and notions, but all must be subjected to critical scrutiny before we accept them. This process, the 'use of impressions', is, like the Socratic *elenchos* (see Socrates §§2-3), internalized, and it is the most important moral practice which Epictetus urges on his audience.

Other philosophical schools appear frequently in Epictetus' lectures; he does not merely preach to the converted. He takes an anti-Epicurean stance, attacking Epicurus' neglect of logic, his denial of providence, his hedonism, and most of all the anti-social implications of his egoism (see Arcesilaus; Carneades; Epicureanism §§10-11). The Academics are also attacked for their scepticism. As one might expect, Epictetus has an ambivalent attitude to Cynics. He rejected the extremes of their life-style. But from another point of view, their moral autonomy made them an ideal for which to strive. It was inevitable that Epictetus should look up to the Cynics, whose very extremism turned them into symbols of the values which he held most dear. All human beings, he thought, must strive for inner freedom; the independent and even anti-social behaviour of the Cynics expressed in a socially visible form the ultimate goal of moral life for Epictetus.

Epicureanism

Epicureanism is one of the three dominant philosophies of the Hellenistic age. The school was founded by Epicurus (341-271 BC*). Only small samples and indirect testimonia of his writings now survive, supplemented by the poem of the Roman Epicurean Lucretius, along with a mass of further fragmentary texts and secondary evidence. Its main features are an anti-teleological physics, an empiricist epistemology and a hedonistic ethics.*

Epicurean physics eveloped out of the fifth-century atomist system of Democritus. The only per se *existents are bodies and space, each of them infinite in quantity. Space includes absolute void, which makes motion possible, while body is constituted out of physically indissoluble particles, 'atoms'. Atoms are themselves further measurable into sets of absolute 'minima', the ultimate units of magnitude. Atoms are in constant rapid motion, at equal speed (since in the pure void there is nothing to slow them down). Stability emerges as an overall property of compounds, which large groups of atoms form by settling into regular patterns of complex motion. Motion is governed by the three principles of weight, collisions and a minimal random movement, the 'swerve', which initiates new patterns of motion and obviates the danger of determinism. Atoms themselves have only the primary properties of shape, size and weight. All secondary properties, for example, colour, are generated out of atomic compounds; given their dependent status, they cannot be added to the list of* per se *existents, but it does not follow that they are not real. Our world, like the countless other worlds, is an accidentally generated compound, of finite duration. There is no divine mind behind it. The gods are to be viewed as ideal beings, models of the Epicurean good life, and therefore blissfully detached from our affairs.*

The foundation of the Epicurean theory of knowledge ('Canonic') is that 'all sensations are *true' - that is, representationally (not propositionally) true. In the paradigm case of sight, thin films of atoms ('images') constantly flood off bodies, and our eyes mechanically register those which reach them, neither embroidering nor interpreting. These primary visual data (like photographs, which 'cannot lie') have unassailable evidential value. But inferences from them to the nature of external objects themselves involves judgment, and it is there that error can occur. Sensations thus serve as one of the three 'criteria of truth', along with feelings, a criterion of values and psychological data, and* prolēpseis*, naturally acquired generic conceptions. On the basis of sense evidence, we are entitled to infer the nature of microscopic or remote phenomena. Celestial phenomena, for example, cannot be regarded as divinely engineered (which would conflict with the* prolēpsis *of god as tranquil), and experience supplies plenty of models adequate to explain them naturalistically. Such grounds amount to consistency with directly observed phenomena, and are called* ouk antimarturēsis*, 'lack of counterevidence'. Paradoxically, when several alternative explanations of the same phenomenon pass this test, all must be accepted as true. Fortunately, when it comes to the foundational tenets of physics, it is held that only one theory passes the test.*

*In ethics, pleasure is the one good and our innately sought goal, to which all other values are subordinated. Pain is the only bad, and there is no intermediate state. Bodily pleasure becomes more secure if we adopt a simple lifestyle which satisfies only our natural and necessary desires, with the support of like-minded friends. Bodily pain, when inevitable, can be outweighed by mental pleasure, which exceeds it because it can range over past, present and future enjoyments. The highest pleasure, whether of soul or of body, is a satisfied state, 'static pleasure'. The short-term ('kinetic') pleasures of stimulation can vary this state, but cannot make it more pleasant. In striving to accumulate such pleasures, you run the risk of becoming dependent on them and thus needlessly vulnerable to fortune. The primary aim should instead be the minimization of pain. This is achieved for the body through a simple lifestyle, and for the soul through the study of physics, which offers the most prized 'static' pleasure, 'freedom from disturbance' (*ataraxia*), by eliminating the two main sources of human anguish, the fears of god and of death. It teaches us that cosmic phenomena do not convey divine threats, and that death is mere disintegration of the soul, with hell an illusion. Being dead will be no worse than not having yet been born. Physics also teaches us how to evade determinism, which would turn moral agents into mindless fatalists: the indeterministic 'swerve'* doctrine *(see above), along with the logical doctrine that future-tensed propositions may be neither true nor false, leaves the will free.*

Although Epicurean groups sought to opt out of public life, they respected civic justice, which they analysed not as an absolute value but as one perpetually subject to revision in the light of changing circumstances, a contract between humans to refrain from harmful activity in their own mutual interest.

1 The Epicureans

For the foundation and nature of the Epicurean school, and for Epicurus' own writings, see Epicurus. After Epicurus' death in 271 BC the school continued to flourish, at Athens and in other centres around the Mediterranean, for at least five centuries. Although there were numerous developments and schisms, these were always moderated by appeals to the scriptural authority of Epicurus' own writings and those of his close collaborators Metrodorus, Polyaenus and Hermarchus.

The surviving writings of Epicurus include *Letter to Herodotus*, *Letter to Pythocles*, *Letter to Menoeceus*, *Kyriai doxai* (*Key Doctrines*) - all preserved in Book X of Diogenes Laertius - and parts of *On Nature*. In addition, we have from the first century BC the Epicurean poem of Lucretius, dealing mainly with physics, and numerous fragmentary papyri of the Epicurean Philodemus, excavated from a villa at Herculaneum. Finally, there is the second-century AD philosophical inscription of the Epicurean Diogenes of Oenoanda, which contains much supplementary information.

2 Foundations of physics

Whatever the universe consists of must be permanent. Nothing comes into being out of nothing or perishes into nothing - two fundamental principles widely regarded as indubitable, but defended by the Epicureans on empirical grounds (Lucretius I 159-264): literal generation would be incompatible with the observed regularities of natural processes, such as the dependence of organic growth on the right material conditions; and literal annihilation would, given the infinity of past time, by now have ensured that nothing at all was left. Nor can the universe (the 'all') be changed by addition or subtraction, since by definition it has nothing outside it that could enter or into which bits could escape.

Next comes a statement of what the universe does consist of: bodies and space (*Letter to Herodotus* 39-40). This is taken to be self-evident, that is, underivatively known and unchallengeable. The reasoning is no doubt that bodies are the things which most obviously have independent existence; and that since that independence is most evident in their ability to move in space, the bits of space which they vacate as they move must exist independently of *them*.

Space is at this stage simply presented as what the bodies are in, and what they move through - a three-dimensional extension which persists whether occupied or unoccupied. When occupied it gets called 'place', when unoccupied 'void' (*kenon*, literally the 'empty'), and when things move through it 'room' (*chōra*, etymologically linked by Epicurus with *chōrein*, 'go'). Epicurus prefers to use these familiar terms rather than a generic one for 'space', for which Greek has no precise word (the concept itself being one which had emerged only gradually, with Epicurus perhaps the first to isolate it clearly), and which he manages to capture only by his invented phrase 'intangible nature' (*anaphēs physis*). That there is void, that is, that contrary to the majority ancient view some space is altogether empty, is argued by appeal to such phenomena as motion and permeation. Motion cannot be accounted for, it is argued (Lucretius I 370-83), by the alternative hypothesis of complementary redistribution of matter on the model of a fish exchanging places with the water when it swims. Even the fish would be stuck fast unless there were some void to break the deadlock. Otherwise it would be unable to move until the water had cleared a path for it, or the water until the fish had cleared a path for it.

As for body, it remains for now largely unanalysed, beyond a set of arguments to show that it must exist microscopically as well as macroscopically: its underlying atomic structure cannot be demonstrated until it has been shown that body and space are the sole constituents of the universe. And the next move is to show just that. First, body and space are analysed as contradictory opposites: only three-dimensional things exist *per se*, and if these are resistant they must be body, if non-resistant void (Lucretius I 430-9). This is the positive proof that body and space are not only irreducibly distinct but also jointly exhaustive. There then follows a supplementary argument (Lucretius I 449-82), in which all other contenders for *per se* existence - including properties and time - are written off as secondary attributes, parasitic on body and/or space. None of these could exist independently of bodies and/or space. Time is dependent on change, that is, on moving bodies. And even facts about the past (for example, that there was a Trojan War), which might seem to outlive the bodies (Agamemnon and others) of which they are true and therefore to acquire independent existence, are truths about places which still persist (Troy, Mycenae and so on), or, if you prefer, about the universe.

Only now that it is fully established can the body-space dualism be deployed to show that at the lowest level of analysis there will be not only portions of empty space uninterrupted by body but also portions of body uninterrupted by empty space - and therefore, since there is no third thing, totally uninterrupted. Being perfectly solid, these are 'atoms', literally 'uncuttables'. The capacity of a body to disintegrate is directly correlated to the amount of void within it; therefore a body containing no void at all is altogether indestructible (Lucretius I 511-39). That there are such bodies is confirmed both by the evident fact that matter is not completely annihilated by fragmentation, and by the observed regularities of nature, which imply that something altogether unchanging underlies them.

Having mapped the universe out into space occupied by discrete portions of body, Epicurus adds that both space and body are infinite in extent (*Letter to Herodotus* 41-2, Lucretius I 958-97). First, the infinity of the universe itself (a highly controversial thesis in antiquity, rejected by both the Platonist and the Aristotelian tradition) is argued by appeal to the notion of a limit: it could only be limited if there were something beyond it to limit it, and the notion of the universe (the 'all') precludes that. (Lucretius adds the time-honoured argument: what if I go to the supposed edge of the universe and throw something?) Second, it is argued that each of the two constituents of the universe must also, taken on its own, be infinite: finite body in infinite space would be too dissipated to form compounds, while infinite body in finite space would simply not fit.

3 Minima

The fifth-century atomists (see Atomism, ancient; Leucippus; Democritus §2) had first introduced atoms at least partly to circumvent the puzzles that Zeno of Elea (§§4-6) had derived from the supposition of infinite divisibility: any magnitude will, as the sum of infinitely many parts, be infinitely large; and motion will be impossible, since it will require the traversal of infinitely many sub-distances. But if atoms, as seems inevitable given their varying shapes and sizes, are not the smallest possible magnitudes but simply indissoluble lumps, it is hard to see that this kind of indivisibility can do anything to thwart Zeno: each atom will consist of infinitely many parts, and threaten to be infinitely large and/or untraversable.

Epicurus (*Letter to Herodotus* 56-9) starts by making the first clear distinction in ancient thought between (1) things which are physically indivisible, and (2) those which modern scholarship sometimes calls theoretically, conceptually or mathematically indivisible, but which in ancient usage are called either 'minimal' (*elachista*) or 'partless' (*amerē*). (For Epicurus' main predecessor in a theory of type (2), see Diodorus Cronus §2.) Not only, Epicurus says (*Letter to Herodotus* 56), (1) can things not be 'cut' to infinity (a reference to atoms, which are physically 'uncuttable'), as proved earlier, 'but also (2) we must not consider that in finite bodies there is *traversal* [moving along something part by part] to infinity, not even through smaller and smaller parts [that is, not even in a convergent series such as $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \ldots$]'. Otherwise, he warns, Zenonian consequences will ensue.

By showing that a finite body cannot contain an infinite number of parts, Epicurus considers that he has established the existence of an absolutely smallest portion of body, which henceforward he calls 'the minimum (*elachiston*) in the atom'. Clearly it cannot be larger than an atom, or it would not be a minimum, so it must be either an entire atom or part of one. (For reasons which emerge later, it must in fact be the latter.) The idea that an extended magnitude like an atom consists of minimal or partless units is designed to avoid Zenonian paradoxes, but, as Aristotle had pointed out in *Physics* VI, it generates paradoxes of its own. In particular, it is hard to see how two partless items can be adjacent, since they cannot touch either part to part (they do not have parts) or whole to whole (or they would be co-extensive, not adjacent). Epicurus answers brilliantly with the analogy of the 'minimum in sensation' - the smallest magnitude you can see. Any larger visible magnitude consists of a precise number of these minima, which are seen as adjacent without touching in either of the two ways offered by Aristotle, but, as Epicurus puts it, 'in their own special way'. This provides a model which is readily transferable to the 'minimum in the atom'.

But it also follows, of course, that *any* extended magnitude will consist of an exact number of minima, since after analysis into minima there could not be a fraction of a minimum left over. This makes all magnitudes commensurable, and conflicts with the geometers' recognition of incommensurable lengths, for example, the side and diagonal of a square. So much the worse for geometry, was the conclusion of Epicurus and his collaborator Polyaenus, himself formerly a distinguished geometer. They concluded, at least provisionally, that geometry is false.

In one respect the analogy between the sensible and actual minimum fails. Visible minima are capable of independent motion (for example, a falling object viewed at a suitable distance might be a sensible minimum), but actual minima are not, says Epicurus. This perhaps reflects Aristotle's argument in *Physics* VI 10 that a partless entity (he is thinking especially of a geometric point) could not move except incidentally to the motion of a larger body. At all events, it follows that, since atoms move, no atom consists of just one minimum.

Atoms must vary widely in shape and size in order to account for the large range of phenomena (Lucretius II 333-477). But they cannot vary indefinitely, since out of a finite set of minima only a finite number of shapes can be formed. Being partless, minima cannot be partly adjacent, so two minima can only be arranged in one shape, three minima in only two shapes, and so on (Lucretius II 478-531).

4 Motion

Surprisingly, atoms never stop moving, even within a compound object, since the medium through which they move is void, which can offer them no resistance. More surprisingly, for the same reason they move at a vastly greater speed than any familiar motion through an obstructive medium such as air; even than sunlight, which is seen to spread from horizon to horizon virtually instantaneously (Lucretius II 142-64). More surprisingly still, they all move at equal speed, since in a vacuum, unlike air, there is no resistance from the medium to slow down the lighter ones more than the heavier ones (*Letter to Herodotus* 61). In stating all these claims, Epicurus is accepting paradoxical consequences of the hypothesis that void exists, consequences which Aristotle had drawn (*Physics* IV) in the belief that they were sufficiently absurd to discredit the hypothesis. Moreover, the equal speed of atoms was confirmed by another objection Aristotle thought he had found to atomism (*Physics* VI 2): if there is a minimal magnitude, there can be no differences of speed, because then in the time the faster object took to travel one minimum the slower one would, impossibly, have to travel less than one minimum. Epicurus welcomed this argument, along with the conclusion Aristotle thought absurd, because his theories of void and minima now offered two independent grounds for the same conclusion, that atoms move at equal speed.

The apparent lack of fit between these findings about atoms and the variable speed of macroscopic motions is explained as follows (*Letter to Herodotus* 62). Even in a compound object the individual atoms are perpetually moving, but in tight and regular cyclical patterns which make the complex as a whole stable. Phenomenal differences of speed, say between two runners, represent merely the aggregate motions of the atoms in each over an observed period of time.

There are three causes of an atom's motion. The first is its own weight, interpreted as an inherent tendency to move downwards (see §8). The second is collisions with other atoms, which can deflect an originally downward motion along any number of new rectilinear trajectories, thus generating the patterns of motion of which compounds are born.

The third cause of atomic motion is the 'swerve' (*parenklisis*), whereby an atom may shift from its rectilinear trajectory onto an adjacent one - a displacement sideways by a distance of one minimum (there being no smaller distance). This happens 'at no fixed place or time', meaning that the occurrence of a swerve is causally undetermined. The theory, derided by Epicurus' opponents but now recognized as comparable in its implications to modern quantum indeterminism, looks like a drastic solution requiring a drastic problem. Two such problems are recorded (Lucretius II 216-93). First, since all atomic motion starts out as vertical and equal in speed, without a swerve no collisions would ever have started, and hence no world could have been formed. It may be doubted whether this was a sufficiently pressing problem to motivate an abandonment of universal causality: given the infinite past history of the universe, Epicurus had no need to posit a very first collision; in which case every collision could have been explained as the effect of previous ones. The second problem seems to have been the real motivation of the swerve: if all atomic motion is causally determined, free will becomes impossible (see §12).

5 Qualities

Atoms themselves have only the primary or ineliminable features of body: size, shape and weight. They lack the secondary properties of colour, flavour and so on. The ground for this parsimony is (*Letter to Herodotus* 54-5) that secondary properties are in their nature changeable, whereas atoms have been posited as the enduring entities which underlie change. Atomism instead treats colour and the like as purely macroscopic properties, caused by the

individual shapes and overall arrangement of the constituent atoms in a compound body, and changed if that arrangement changes. Lucretius frequently compares the explanatory economy of this system to that of the alphabet, capable of generating endless different words simply by rearranging a modest stock of letters. In practice the crudely sketched atomistic explanations of macroscopic properties owe more to the shapes than to the arrangement of a thing's constituent atoms (fluids consist of smaller and rounder atoms, sweet things of smoother ones…), although the degree of separation between atoms plays some part.

There are two kinds of properties (*symbebēkota*). 'Permanent accompaniments' (Greek *ta aidion parakolouthounta*, Latin *coniuncta*) are essential to a thing's very existence, for example, tangibility for body and heat for fire, while accidents (*symptōmata*) are non-essential, for example, slavery or poverty for a human being. It is crucial to note that no ontological priority is implied for the properties of atoms over those of phenomenal bodies. The earlier atomist tradition had tended to treat atoms and void alone as real, with phenomenal properties mere arbitrary constructions placed upon them by the human mind and sense organs. This had led atomism in the direction of epistemological scepticism, a tendency which Epicurus himself strenuously resists. In discussing the status of properties (*Letter to Herodotus* 68-71), he emphasizes that although undoubtedly different from the *per se* existents, body and void, they are no less real for that. (The second-generation Epicurean Polystratus adds that even relative properties such as 'beneficial' and 'harmful', often decried as unreal by sceptics, have clear causal effects.) Accidents, in fact, have no existence at the microscopic level (*Letter to Herodotus* 70), and yet are real. This is a clear indication that Epicurus is consciously opposed to the atomist reductionism of his predecessors: colours and other accidents are real, yet irreducibly different from atomic structures. Although atomic structures are *causally* prior to the phenomena which they generate, they are in no way *ontologically* privileged over them.

6 The criteria of truth

Since, then, Epicurus' version of atomism allows the reality of sensible properties, he does not inherit Democritus' motive for casting doubt on the veracity of sense-perception (see Democritus §3). And indeed for Epicurus the primary 'criterion of truth' is the senses: 'All sensations are true.'

The soul is an atomic structure spread throughout the body, but with a command centre which houses rational thought (these can be considered functionally, although not anatomically, equivalent to the nervous system and brain, respectively). A sensation is the soul's mechanical but conscious registering of the phenomenal properties of an external body. In the paradigm case of sight, this occurs because the outer layers of bodies are constantly streaming off them in all directions, taking the form of 'images' (Greek *eidōla*, Latin *simulacra*), atom-thin films of matter which more or less preserve their colour and shape in transit (*Letter to Herodotus* 49-52, Lucretius IV 26-268). Streams of these can enter the eye, producing vision; isolated ones can also directly enter the mind, asleep or awake, and enable it to visualize objects (Lucretius IV 722-822, 962-1036). Importantly, *any* act of picturing, by the eyes or the mind, is the registration of one or more images arriving from outside. The infallibility of the senses consists in their mechanical registering of these images, without adding, subtracting, embroidering or interpreting. A useful analogy is photography, which 'cannot lie' because it merely records mechanically the patterns of light arriving at the camera lens, and leaves it to us to interpret what they represent. All sensations are bona fide evidence about the external world. All error lies in the 'added opinion' (*to prosdoxazomenon*) by which the mind interprets these data. Note that truth here is representational, not propositional: the sensation is true because it accurately represents the physical data reaching the sense organ. The opinion based on it may be regarded as true or false according to whether or not it succeeds in representing accurately the state of affairs which caused the sensation. Even in a case of outright delusion it is the mind which, because deranged, misinterprets the perfectly accurate impressions which reach it. As for the more important counterexamples to the theory, those of optical illusions, the paradigmatic case is the square tower which looks round at a distance. The images start out square, but because of the distance which they must travel through obstructive air they are rounded on arrival at the eyes (if this is too crude to be credible, substitute the image of a coin, oval due to perspective). Therefore vision is accurately registering the images as they are on arrival. This is a correct, not a misleading, view of a distant tower, and to call it a case of mis-seeing, says Epicurus (Sextus Empiricus, *Against the Professors* VII 206-10), is like saying that you are mishearing someone across the room just because you are not hearing their voice as it would sound inside their mouth.

The veracity of the senses is not, as many hold, impugned by their ability to conflict with each other. Strictly

speaking, no two sensations are commensurable. If sight and touch differ about the shape of an object, that is because sight reports the shape of a colour patch, touch the shape of a body. If two visual sensations of the same object conflict, as in the case of the tower, that is because they are reporting two different kinds of colour patch, mediated by different quantities of intervening air.

The photographic reliability of the senses is what makes them not only true but a criterion of truth. However, when Epicurus appeals to the evidence of the senses as his ultimate criterion, it is not usually to these raw sensations, still awaiting interpretation by the mind, but to facts directly attested by them, for example, that things move, or that round objects move more readily than jagged ones. He regularly talks as if these interpreted sensations acquire the self-evident veracity which initially belongs only to the raw impressions.

The second criterion of truth is *prolēpsis*, or ‘preconception’ - a key term in ancient epistemology, first introduced by Epicurus. The *prolēpsis* of a thing is an instinctively acquired generic grasp of its nature, which enables you to recognize instances of it and is available for analysis in conceptual inquiries. Your *prolēpsis* of a human being, acquired unreflectively by accumulated past experience, enables you both to recognize humans when you meet them, and in the course of an inquiry to establish their essential features, for example, rationality and mortality. (When *prolēpseis* are said to be built up from past sensory experiences, these must again be interpreted sense-impressions, not raw ones.) Other *prolēpseis* appealed to in Epicurean arguments include those of god, body, utility and responsibility. *Prolēpseis* are taken to be common to all human beings, and therefore to function like a set of shared intuitions which we can hope to rediscover beneath our acquired false beliefs and to use as common ground for joint philosophical inquiry

The third criterion of truth is feelings (*pathē*), which generically divide up into just two kinds: pleasure and pain. As such, feelings certainly function as criteria of *value*, since Epicurus equates good with pleasant, bad with painful. But they also provide the introspective data on which Epicurus founds his psychological theory (*Letter to Herodotus* 63).

7 Scientific method

Starting from the direct data of the senses, broader and less accessible truths can be established. Epicurus apparently divided the accessing process into two classes, ‘attestation’ (or ‘witnessing’, ‘confirmation’, and so on: *epimarturēsis*) and ‘non-contestation’ (or ‘lack of counterevidence’, ‘non-confirmation’, and so on: *ouk antimarturēsis*). Attestation plays a relatively minor part in scientific inference, since it seems confined, if not to truths directly supplied by the senses, at most to inductive generalizations derived from these. The main concern of Epicurean science is the extension of such knowledge beyond the realm of direct experience, into inaccessibly remote regions of the universe such as the heaven or other worlds, and into the microscopic realm of atoms and void. Here theories cannot be directly confirmed, but are tested instead by their *consistency* with empirical data: hence ‘non-contestation’ by phenomena.

Not that *mere* consistency with experience is enough to establish truth. A theory is only entertained in the first place if it has some explanatory power or recommends itself in some comparable way. But there may be several alternative theories of equal merit in this regard, and if so each must be tested for ‘non-contestation’ by phenomena, to see which survives. There are many intrinsically credible general theories of matter, for example, including the four-element theory and the monistic fire theory of Heraclitus, and likewise many intrinsically plausible theories of vision, and so on. But all except the Epicurean theory fail somehow to be consistent with the entire range of phenomena against which they are tested.

In some other cases, however, especially astronomical ones, Epicurus admits that two or more rival theories survive the test. This might be considered an indication that the consistency test can at best prove a theory possible, not true. But Epicurus insists that in such cases all the successful theories are indeed true. Sometimes this means that several different explanations of the same phenomenon - for example, thunder, or the generation of perceptual ‘images’ (see §6) - operate concurrently in our world. In other cases it means no more than that, given the intrinsic possibility of the hypothesized causal process, it must operate *somewhere* in the infinite universe, even if not here.

All such ‘sign-inferences’ (*sēmeiōseis*) are from something evident to something non-evident. Often this is from the macroscopic to the microscopic: either causal inference from a macroscopic effect to a microscopic cause (for

example, from the observed regularities of nature to the existence of unchangeable elements; see §2), or analogical inference (for example, from the mobility of observed spheres to that of spherical atoms, see §5). Others are from the macroscopic to the macroscopic: either from accessible to inaccessible entities or events (for example, from the mechanism of the water-wheel to the rotation of the stars), or from the present to the past or future (for example, from the current structure of a social institution like law or language to its historical origin, or from the impermanence of familiar compounds to the future destruction of the world).

The nature and validity of such sign-inferences is debated between the Epicureans and the Stoics in Philodemus, *On Signs*, including an important controversy about the justification of induction.

8 Cosmology

Epicurus argues that there can be no creating or controlling divinity (see §9), and that our world, one of infinitely many, is an accidental and temporary product of large-scale atomic collisions (for the role of the 'swerve' in this, see §4). Apparent evidence of divine creation can be explained mechanistically. Animal parts, for instance, however well suited to their uses, came into existence accidentally before those uses were conceived. In the early days of life on earth many non-viable creatures were generated, but did not survive (Lucretius V 837-77; a widely admired anticipation of Darwinian survival of the fittest). Even human institutions such as language and law, often attributed to divine benefactors, are formalized versions of modes of behaviour with purely natural origins in human need and instinct.

Epicurus' account of the world's structure is largely Presocratic in inspiration. Since atoms have no inherent attractive powers, he cannot accept the geocentric cosmologies of Plato, Aristotle and others, in which heavy stuffs tend not strictly downwards but inwards towards the centre. The direction 'down' is itself taken to be an absolute one, so that throughout the universe objects fall parallel to each other, rather than towards the centre of a spherical earth. For him the earth's stability depends not on its being at the centre (in infinite space there is no centre) but on the cushioning effects of the air beneath it. In a notorious passage (I 1052-82) Lucretius dismisses as ill-conceived the geocentrists' impressively accurate description of the antipodes.

9 God

That our world cannot be a product of divine craftsmanship is argued on several grounds (especially Lucretius V 156-234). Quite apart from the world's obvious imperfection, and the difficulty of finding a motive for its creation by already blissfully happy beings, the true conception of a god is incompatible with the role of cosmic administrator. A god is a supremely tranquil being, whereas the burdens of government include attitudes of anger, favour and worry.

How do we know that god is like this? In Epicurus' view there is a natural conception (*prolēpsis*: see §6) of god as a blessed and immortal anthropomorphic being, a conception shared by all human beings, even though in most it has been obscured by a veneer of false beliefs, for example, that the gods are vengeful, or that they govern our lives, turn the heavens and so on. People tend to endow god with their own moral values, especially the competitive values of political society, and by the same token the Epicurean reversion to the true conception of divinity as tranquil and detached is also a rediscovery of the natural human goal, tranquillity (see §10). Epicurus is insistent that 'there are gods', and even that they should be worshipped, but as an act of veneration for a life to which we ourselves aspire, not in the hope of appeasement.

But how can there be gods, if that means literally (that is, biologically) immortal beings? If according to Epicureanism nothing exists independently except bodies and void, and a god can hardly be either void or a single atom, a god must be an atomic complex. But it is a cardinal tenet that no compound body can be everlasting (Lucretius III 806-18).

Here scholarly opinion divides. The majority seek special ways in which an Epicurean god can nevertheless be literally immortal, by living in sheltered regions beyond our world and by consisting of constantly replenished streams of visual 'images' (on which see §6). Others (following Sextus Empiricus, *Against the Professors* IX 43-7) favour an idealist interpretation of Epicurean theology, whereby god, properly understood, just is our own idealization of a happy human life. On this view, when god is said by the sources to consist of visual 'images', this is simply because according to Epicurean cognitive psychology (§6) *all* imagination consists in the apprehension

of images which enter us from outside. The images which provide the raw material for our conception of god need not flow to us from any objectively real divine being, but may be ordinary locally generated human images. Epicurus' main point in identifying god with a stream of images was apparently the negative one of denying that god is a 'solid body' at all (Cicero, *On the Nature of the Gods* I 49).

Epicurus seems to have spoken repeatedly about how we should *think* of god as being, behaving and so on, which in itself is equally compatible with the realist and the idealist interpretation. Equally powerless to settle the dispute is the insistence of Epicurus and his followers that their position is theistic, or that of his critics that it is atheistic. But on either reading it should be clear that the importance of god in Epicurus' system is not cosmological but ethical. Having a correct conception of god is identical with moral enlightenment.

10 Hedonism

Another 'innate' human attitude, along with the *prolēpsis* of god, is the pursuit of pleasure as the only positive value, or 'end' (*telos*). Epicurus argues that the behaviour of the newborn, and even of non-human animals, confirms that to maximize pleasure and minimize pain is the natural and primal drive (Cicero, *On Ends* I 30). Just as physics began with the crude mapping out of *per se* existents into bodies and space (§2), so ethics starts with the mapping out of all intrinsic values into pleasure and pain. And again as in physics, the next move consists in showing these two items to be jointly exhaustive: the absence of pain is itself pleasure, and there is therefore no intermediate state (Cicero, *On Ends* I 37-9).

This controversial thesis goes to the heart of Epicurus' ethics. In his view, most human misery results from ignorance of how to quantify pleasure. Where some hedonists, especially the contemporary Cyrenaic School (see Cyrenaics §4), had recommended the constant renewal of pleasure through self-indulgence, Epicurus observes that this accumulation does not increase the total of pleasure beyond that achieved when all pain has gone, but only 'varies' it. Freedom from pain is itself already a supremely pleasant state. The pursuit of luxury, far from increasing pleasure, enlarges your desires and leaves you needlessly vulnerable to the whims of fortune.

In his physics, Epicurus had completed the division of *per se* existents into bodies and void by showing that other claimants to *per se* existence, such as properties and time, are in fact parasitic on bodies for their existence. Likewise in ethics, he now examines the non-hedonic values which others assert, such as virtue, and argues that they are in fact valued not for their own sake but as instrumental means to pleasure (Cicero, *On Ends* I 42-54).

It remains to fill out the prescription for the maximization of pleasure, that is, to sketch the ideal Epicurean life. This involves calculating the relative roles of bodily and mental pleasures, and of static and 'kinetic' pleasures. Bodily feeling is in a way focal, since mental pleasure and pain consist ultimately in satisfaction and dissatisfaction, respectively, about bodily feeling. For instance, the greatest mental pain, namely fear, is primarily the expectation of future bodily pain (which is the main ground, and a mistaken one, for the fear of death). But although mental feelings ultimately depend on bodily ones, and not vice versa, mental feelings are a more powerful ingredient in an overall good life. Someone in bodily pain - which may be unavoidable - can outweigh this by the mental act of reliving past pleasures and looking forward to future ones. It is this ability to range over past and future that gives mental feeling its greater power. But misused, especially when people fear everlasting torture after death, it can equally well become a greater evil than its bodily counterpart.

Static pleasure is the absence of pain. The bodily version of it is called 'painlessness' (*aponia*), the mental version 'tranquillity' (*ataraxia*, literally 'non-disturbance'). Tranquillity depends above all on an understanding of the universe, which will show that contrary to the beliefs of the ignorant it is unthreatening. (This is, strictly speaking, the sole justification for the study of physics.) Kinetic pleasure is the process of stimulation by which you either arrive at static pleasure (for example, drinking when thirsty) or 'vary' it (for example, drinking when not thirsty). There are mental as well as bodily kinetic pleasures, for example, (perhaps) the 'joy' of resolving a philosophical doubt or holding a fruitful discussion with friends. Although kinetic pleasures have no incremental value, Epicurus does apparently consider them an essential part of the good life. This is particularly because the mental pleasure which serves to outweigh present pain will inevitably consist in reliving past *kinetic* pleasures and anticipating future ones. So a successful Epicurean life cannot be monotonous, but must be textured by regular kinetic pleasures. In the letter written on his deathbed, Epicurus claimed that despite the intense bodily pains this was the happiest day of his life, because of all the past joys of philosophical discussion that he could relive.

At the same time, these kinetic pleasures must be carefully managed. Some desires are natural, others empty. The latter - for example, thirst for honours - should not be indulged, because their satisfaction will bring either no pleasure or a preponderance of pain over pleasure. Even of the natural ones, some are non-necessary. For instance, the desire for food is necessary, but the desire for luxurious food is not. In order to be maximally independent of fortune, it is important to stick primarily to the satisfaction of natural and necessary desires. But occasional indulgence in those kinetic pleasures which are natural but non-necessary has a part to play, so long as you do not become dependent on them. True to this principle, Epicurean communities lived on simple fare, and even trained themselves in asceticism, but held occasional banquets (see Epicurus §3).

11 Social values

Ancient ethics does not problematize altruism as such, but it does seek the moral foundations of two specific forms of altruism: justice, that is, respecting the interests of your fellow citizens; and friendship. Given that Epicurean hedonism is egoistic - that all your choices as an agent aim at your own pleasure - is it possible to put someone else's pleasure before your own?

Epicurus analyses justice not as an absolute value but as a contractual relation between fellow citizens, its precise character engendered by current social circumstances (*Key Doctrines* 31-7). Sometimes it proves mutually advantageous to abstain from forms of behaviour which harm others, in return for a like undertaking from them. So long as such a contract proves socially advantageous, it is correctly called 'justice'. It imposes no moral obligation as such, and the ground for respecting it is egoistic - that even if you commit an injustice with impunity the lingering fear of being found out will disrupt your tranquillity (*Key Doctrines* 17, 35).

With regard to his own philosophical community, Epicurus attached positive value to justice and to the specific laws which enforced it not because philosophers need any restraint from wrongdoing but because they need protection from the harm that others might inflict. 'Do not take part in politics' was an Epicurean injunction, political ambition being a misguided and self-defeating quest for personal security. But the school nevertheless upheld the need for legal and political institutions, and sought to work within their framework.

Where the political life fails to deliver personal security, friendship can succeed. The very foundation of the Epicurean philosophical community was friendship, of which the mutual dealings of Epicurus and his contemporaries were held up as an ideal model by their successors. Unlike justice, friendship is held to have intrinsic value - meaning not that it is valuable independently of pleasure, but that it is intrinsically pleasant, not merely instrumentally pleasant like justice. Moreover, the pleasure lies in altruistic acts of friendship, not merely in the benefits received by way of reciprocation.

Later Epicureans were pressed by their critics for a more precise reconciliation of friendship with egoism, and developed the position as follows (Cicero, *On Ends* I 66-70). According to one group, it is indeed for our own pleasure that we form friendships, and it is as a means to this, not ultimately for our friends' sake, that we share their pleasure and place it on a par with our own. A second group veered away from egoism: although friendship starts out as described by the first group, the outcome is something irreducibly altruistic, whereby we come to desire our friends' pleasure purely for their sake. A third group sought to restore egoism: the second group is right, but with the addition that friendship is a symmetrical contract, analogous to justice: *each* friend is committed to loving the other for the other's own sake.

12 Free will

Epicurus was arguably the first to make free will a central philosophical issue (see Free will). He takes it that determinism must be false. It is incompatible with basic moral attitudes; the data of self-awareness falsify it; and it is a position which cannot even be argued coherently, since to enter an argument is to assume that both parties to the debate are responsible for their beliefs and could adopt others (*On Nature* XXV).

Determinism is arrived at by two routes, each of which must therefore contain a false supposition. The first route is via a logical law, that of bivalence: since all propositions, including those about the future, are either true or false, if it is already false that a given event will occur, it cannot occur, and if true, it cannot fail to occur. Therefore everything that occurs occurs of necessity. Epicurus' response is (like Aristotle's in *De interpretatione* 9, as widely interpreted) to reject the law of bivalence as regards future-tensed propositions. Predictions whose accuracy

depends on human decisions yet to be made are, at the time of utterance, neither true nor false.

The second route is physical. We - our souls as well as our bodies - consist entirely of atoms, which move according to mechanical laws. How then can anything be genuinely 'up to us'? Are we not automata, our actions the outcome of infinite atomic causal chains? This time the Epicurean response is that the laws of atomic motion are not after all entirely deterministic. Atoms' motion through weight and blows is mechanical and invariable, but there must be a third, indeterministic, aspect of their motion, the minimal 'swerve' (see §4).

But how do swerves help explain free will? The question is much debated by scholars. Epicurus may appear to be merely substituting an unpredictable mechanism for a predictable one, not putting *us* in charge. Perhaps, as with the denial of bivalence, he is merely attempting to remove an obstacle to free will, not to explain it. Whether the swerve enters more directly than this into his account of volition will depend partly on whether he thinks that mental events such as volition are reducible to atomic changes in the soul, in which swerving atoms could play a part. There is in fact strong evidence (*On Nature* XXV) that he regarded mental events as irreducibly different from the soul atoms underlying them, and even as having their own causal efficacy *on* the atoms. (For his rejection of atomic reductionism, see §5 above.) If so, it may be safest to conclude that volition is already by its own nature autonomous - not part of an antecedent causal chain at all - and that this is the primary explanation of free will. Unfortunately its autonomy would be rendered impotent if either the laws of logic or those of physics had already determined our future actions independently of it. Therefore both sets of laws must be so rewritten as to circumvent this danger, and to keep alternative possibilities genuinely open. In the case of physics, the indeterministic swerve just is the most economical realization of that requirement.

13 Death

That the soul must itself be composed of atoms has, in Epicurus' judgment, one very cheering implication. It can easily be shown to perish with the body. Lucretius (III 417-829) presents a whole battery of arguments for this, based not only on the evidence for the soul's dissolubility but also on other indications, such as the continuous parallelism between its development and decay and those of the body. From the finding that there is no conscious survival after death Epicurus concludes that 'death is nothing to us'. To fear your own future non-existence is as groundless as to regret the time when you had not yet been born, and involves the absurdity of imagining yourself being there to witness and lament your own non-existence. To regret that your pleasures will be cut short is to make the computational mistake of supposing that a finite lifespan is *ipso facto* less pleasant than an infinite one. In a brilliant diatribe against the fear of death, Lucretius (III 830-1094) interprets the myths of punishment in the afterlife as allegories for moral malaise in this life, and portrays much human unhappiness, manifested in the vain search for security through wealth and power, as subconsciously nourished by the fear of death.

14 Influence

Epicureanism enjoyed exceptionally widespread popularity, but unlike its great rival Stoicism it never entered the intellectual bloodstream of the ancient world. Its stances were dismissed by many as Philistine, especially its official rejection of all cultural and intellectual activities not geared to the Epicurean good life. It was also increasingly viewed as atheistic, and its ascetic hedonism misrepresented as crude sensualism (hence the modern use of 'epicure'). The school nevertheless continued to flourish down to and well beyond the end of the Hellenistic age. The poets Virgil and Horace had Epicurean backgrounds, and other prominent Romans such as Cassius, the assassin of Julius Caesar, called themselves Epicureans. In the first three centuries of the Roman Empire many writers show some debt to Epicurean thought, including not only the novelist Petronius but even the Stoic Seneca and the Platonist Porphyry. When Marcus Aurelius (§1), Roman emperor AD 161-80, established four official chairs of philosophy at Athens, a chair of Epicureanism was among them. In later antiquity Epicureanism's influence declined, although it continued to provide a target for thinkers, both Christian and pagan, in search of a godless philosophy to attack. Serious interest in it was revived by Renaissance humanists, and its atomism was an important influence on early modern physics, especially through Gassendi.

Epicurus (341-271 BC)

Epicurus of Samos founded the Epicurean school of philosophy. Initially a Democritean, he overhauled Democritus' atomism so radically that his system was soon considered an independent one. He formed three Epicurean communities, the final one at Athens where his school, the Garden, became synonymous with Epicureanism. He and his three leading colleagues wrote voluminously, and their collective works became the school's canonical texts in later generations. Those of Epicurus alone amounted to 300 books (scrolls), including his seminal treatise On Nature. Most were long and technical, but he also composed short digests as an aide memoire*.*

1 Life

Although born on the Aegean island of Samos, Epicurus was the son of an Athenian, Neocles, and hence an Athenian citizen; this entitled him to own land at Athens, where he later established his principal school. While still in Samos he took lessons with a Platonist, Pamphilus, and much of his eventual philosophy can be seen as a reaction against Platonism. Equally formative was his period of study at Teos, although he violently disapproved of Nausiphanes, his Democritean teacher there, and may have been reacting against him in setting out to reshape the atomist tradition (see Atomism, ancient; Democritus). Epicurus famously professed to be self-taught. This was a denial that he had learnt anything from his teachers, Pamphilus and Nausiphanes, and he certainly never disguised his debt to Democritus and other forerunners. He also, in these formative years, developed an admiration for Pyrrho, later to become the patron saint of Scepticism, and may have acquired from his model of practical conduct the ideal of tranquillity which was to become the primary ethical goal in his own system (see Epicureanism §10).

At the age of 31 Epicurus set up his first school, in Mytilene on the island of Lesbos. Soon after that, he moved to Lampsacus (on the west coast of modern Turkey), where he established a second school. There he acquired many of the pupils who were to remain his closest associates for the remainder of his life, including Polyaenus, Metrodorus and his eventual successor Hermarchus. These communities continued to flourish even after 307 BC, when Epicurus and a number of his colleagues moved on to Athens to establish the Garden, thereafter the headquarters of Epicureanism, on a plot of land which he bought just outside the city walls.

2 Writings

Epicurus' writings were voluminous, but now only a few short works survive, along with fragments of others and a great mass of secondary testimonies. *On Nature*, of which fragments survive on papyrus, was his major treatise, written in thirty-seven books over many years, and covering much more than the physical topics which the title suggests. Books I-XIII, probably written before the move to Athens, covered the principal subject matter of physics. Books XIV-XV (dated 301-300 BC) seem to have contained a refutation of other physical theories. Another book (perhaps XXV) is devoted to psychology. Book XXVIII (dated 296 BC) discusses the philosophical role of language. These texts, although difficult and stylistically clumsy, show Epicurus actively at work on his philosophy, responding to opponents and colleagues and entertaining doubts.

Just four short works by Epicurus survive entire, preserved verbatim by the historian of philosophy Diogenes Laertius. The *Letter to Herodotus* is an epitome of *On Nature* I-XIII, on basic physics. The *Letter to Pythocles* epitomizes those parts of his work which dealt with astronomy, meteorology and kindred phenomena. The *Letter to Menoeceus* is an ethical epitome. Finally, the *Kyriai doxai* - 'Key Doctrines' - is a set of maxims on ethics and epistemology, apparently excerpted from individual works. The first four of these were held to sum up the aims of the system, and ran, in the abbreviated form known as 'the fourfold remedy' (*tetrapharmakos*): 'God presents no fears, death no worries. And while good is readily attainable, evil is readily endurable'. The object of these short digests was to aid Epicurus' pupils not so much in understanding his teachings as in memorizing them. They are nevertheless often the best evidence we have to go on. (Another preserved anthology of maxims, the *Vatican Sayings*, less structured than the *Kuriai doxai*, is someone's compilation from the works of Epicurus and other early school members.) None of these digests has a firm date, but there are reasons for placing the *Letter to Herodotus* around 305 BC, and the *Letter to Pythocles* shortly after.

Of his lost works, the most important seem to have been the *Canon*, on the principles of epistemology, and *On the End*, on ethics.

3 The school

In later generations, Epicureans worked from a set of school texts with virtually biblical status. These were the work of four founding fathers - 'the men' (*hoi andres*), as they were known in the school, meaning roughly 'the great men'. The infallible four were Epicurus, Metrodorus, Hermarchus and Polyaenus. Their texts were endlessly scrutinized in disputes about orthodoxy, and their correspondence, along with that of other early Epicureans, was anthologized and studied as a model of the philosophical life. Hermarchus is particularly notable for his detailed account of the origins of law, preserved by Porphyry (*On Abstinence* I 7-12), and Polyaenus was a former mathematician who, in joining the school, came to renounce all geometry as false (see Epicureanism §3).

The Epicurean community was a close-knit one, based on the cult of friendship and the communal study of philosophy, detached from political society without actively opposing it. Unusually for the time, women, children and even slaves and prostitutes participated on equal terms with men. Epicurus taught philosophy to his slave Mys, and Leontion was a prostitute who became a leading member of the group and wrote a work against Theophrastus.

In later generations Epicurus' portrait was ubiquitous, along with the often strikingly similar images of his co-founders. In the manner of the 'hero cults' of classical Greece, regular celebrations were held in their memory - a ritual which Epicurus had already instituted in his own lifetime in remembrance of Metrodorus, Polyaenus and others. It was a cardinal tenet that dead friends should be remembered and celebrated, never mourned. Aside from the feasting on these occasions, the Epicurean lifestyle was an ascetic one, belying the modern meaning of 'epicure'.

Epistemic logic

Modern treatment of epistemic logic began in the 1950s when some philosophers noticed (as scholastics had done before them) certain regularities in the logical behaviour of the concept of knowledge (for example, that knowing a conjunction is equivalent to knowing all its conjuncts) and began to systematize them. Initially these regularities were presented in the form of an axiomatic-deductive system, as in other branches of logic. Later, questions began to be asked concerning the model theory on which such an 'epistemic logic' is based. Still later, the concrete interpretation of this model theory has become an issue. In this way, gradually a bridge has begun to be forged from purely logical questions to such central epistemological questions as those concerning the objects of knowledge, different kinds (or even senses) of knowledge (and their interrelations), the intensional character of knowledge, the de dicto *versus* de re *distinction, and so on.*

1 Propositional epistemic logic

Epistemic logic began as a study of the logical behaviour of the expression 'knows that' (see Propositional attitude statements). One of the main aims of this study is to be able to analyse other constructions in terms of 'knows' by means of '*b* knows that'. This basic notion will be expressed in the notation used here by 'K_b'. (This symbolization is slightly misleading in that, in a formula of the form K_bS, the term '*b*' for the agent (knower) is intended to be outside the scope of '*K*', not inside, as the notation might suggest.) When the knower is the same throughout a sentence (or an argument), the '*b*' is often omitted.

The logic of '*K*' ('knows that') is based on certain simple, pragmatic and epistemological insights. First, what is the use of the notion of knowledge? In what way are you better off when you come to know that *S*? The basic answer is clear. When you know that *S*, you can legitimately omit from consideration all possibilities under which it is not the case that *S*; in other words, you can restrict your attention to the situations in which it is true that *S*. (What is meant by 'legitimately' here is a major philosophical problem. It is essentially tantamount to the well-known problem of defining knowledge (see Knowledge, concept of). For the purposes of epistemic logic, however, we do not have to solve this problem. The structural characterization just given suffices for our purposes, no matter how legitimacy is defined.)

This characterization amounts to making a distinction between two kinds of alternatives (situations; possible worlds) among all the relevant ones. Some possibilities are excluded by what *b* knows. They are the ones that can legitimately be disregarded. Others are not so excluded. They are the ones *b* will have to heed. It should be emphasized that the specification of such a set of admitted situations can be made independently of the psychological, cognitive or sociological peculiarities of the knower in question. Hence epistemic logic does not necessarily involve any subjective or even pragmatic element.

Thus we can see what kinds of structures are to be used in the model theory of epistemic logic (see Model theory). They will be called 'model structures'. They are classes of models of the underlying language minus *K*. Let us consider one of them, say, w_0, in which a potential knower, *b*, exists. Each such w_0 is associated with a number of other models ('possible worlds') w_1 which are not excluded by what *b* knows in w_0. They will be called the epistemic *b*-alternatives to w_0. Thus the basic truth-condition of epistemic logic can be formulated as follows:

K_bS is true in w_0 iff *S* is true in every epistemic *b*-alternative w_1 to w_0.

This definition is of course relative to a model structure. If the *b*-alternativeness relation is called R_b and Ω is the set of all possible worlds, the truth-condition can be expressed as follows:

K_bS is true in $w_0 \in \Omega$ iff *S* is true in each $w_1 \in \Omega$ such that $w_0R_bw_1$.

We can also introduce a notion of epistemic possibility, *P*. Then P_bS means, roughly, 'It is possible, for all that *b* knows, that *S*'. Obviously the following pairs of sentences are logically equivalent: $\sim K_bS$ and $P_b{\sim}S$; $\sim P_bS$ and $K_b{\sim}S$. The truth-condition for epistemic possibility is the obvious one:

P_bS is true in $w_0 \in \Omega$ iff *S* is true in some $w_1 \in \Omega$ such that $w_0R_bw_1$.

Normally it is required that each $w_0 \in \Omega$ be an alternative to itself (for each *b* in w_0). This amounts to requiring

that *b* can know (in w_0) that *S* only if it is true (in w_0) that *S*. Combined with the usual truth-conditions for propositional connectives, we can in this way obtain a semantic basis, complete with a truth-definition, for propositional epistemic logic.

The question of whether the alternativeness relation is transitive or not is equivalent to the question of the logical truth of sentences of the form:

(1) $(\forall x)(K_x S \supset K_x K_x S)$.

Unfortunately, in ordinary discourse, saying that one ‘knows that one knows’ has a number of different meanings, most of which have little to do with (1). Hence the question of whether ‘knowing implies that one knows that one knows’ needs a separate examination which falls only partially within the purview of epistemic logic.

On the basis of these semantic ideas, an epistemic propositional logic is easily developed. It admits of a complete Gentzen-style axiomatization. In such an axiomatization, the rules for ‘Čamp;’ and ‘ $\vee$’ are the usual cut-free ones, while no transfer of formulas between the left-hand side and the right-hand side is allowed. (For simplicity, it is assumed here and in the following that the formulas considered are in negation normal form, that is, that all negation signs in them are prefixed to atomic formulas.) The epistemic rules can then be formulated as follows:

$$\frac{\Gamma, K(S_1 \& S_2) \to \Delta}{\Gamma, KS_1, KS_2 \to \Delta}$$

$$\frac{\Gamma \to \Delta, P(S_1 \vee S_2)}{\Gamma \to \Delta, PS_1, PS_2}$$

$$\frac{S_1, S_2 \to S_3}{\Gamma, KS_1, PS_2 \to \Delta, PS_3}$$

$$\frac{S_1 \to S_2, S_3}{\Gamma, KS_1 \to \Delta, KS_2, PS_3}$$

We also need, of course, suitable structural rules and axioms. The following can serve as such axioms.

$S_1, {\sim}S_1 \to$
$\to S_1, {\sim}S_1$
$S \to S$

A game-theoretic truth-definition is better suited for the purposes of epistemic logic than an ordinary (Tarski-type) one (see Semantics, game-theoretic). In such a definition two players are involved: the proponent and the opponent. At each stage of the game, the two players are considering a sentence and a possible world. The game starts from the world w_0 in which a sentence *S* is to be evaluated. Such a game $G(S; w_0)$ is defined by the following rules:

(G.$\sim$) $G({\sim}S; w_0)$ is like $G(S; w_0)$ but with the roles of the two players reversed. (That is, the proponent of $G({\sim}S; w_0)$ is the opponent in $G(S; w_0)$, and vice versa.)
(G.&) $G((S_1 \ \& \ S_2); w_0)$ begins with a choice by the opponent of S_i ($i =$ 1 or 2) and the rest of the game is as in $G(S_i; w_0)$.
(G.$\vee$) $G((S_1 \vee S_2); w_0)$ likewise, except that the choice of S_1 or S_2 is made by the proponent.
(G.K) $G(K_b S; w_0)$ begins with a choice by the opponent of an epistemic *b*-alternative w_1 to w_0. The rest of the game is as in $G(S; w_1)$.
(G.P) $G(P_b S; w_0)$ likewise, except that the choice is made by the proponent.
(G.atom) Any play of a semantic game will come to an end in a finite number of moves with an atomic sentence or identity *A* and a model (world) *w*. Since the underlying language has been interpreted in *w*, *A* is either true or false. If the former, the proponent of *A* has won and the opponent lost. If the latter, vice versa.

The game-theoretic definition of truth and falsity says that *S* is true (false) in w_0 iff there exists a winning strategy for the proponent (opponent) in $G(S; w_0)$.

2 The semantics of quantified epistemic logic

When we move to *quantified* epistemic logic, we need individuals to serve as values of bound variables. Since we

are dealing with a multiplicity of models (worlds), individuals must in principle be identifiable in more than one of them. ('No entity without identity', to quote Quine.) Hence an individual is, model-theoretically speaking, a 'world line' connecting the roles or embodiments of one and the same individual in several worlds. Less metaphysically expressed, given a model system Ω, an individual is logically speaking a function (an 'individuating function') from models $w \in \Omega$ to the members of the domain $do(w)$ of *w* (see Intensional logics §2). (Since we want to keep our discussion as general as possible, we must allow individuating functions to be partial. In other words, an individual might not be identifiable in all possible worlds.)

A singular term likewise has as its value (bearer), in a given model *w*, a member of $do(w)$. However, these might not be the same individual in two different models. In other words, the values of a singular term *c* in two worlds might not be connected by a world line. The bearers of a singular term *c* in different models are said to be the values of the 'meaning function' associated with *c*. Individuating functions are a special case of meaning functions. Obviously, a meaning function is, like an individuating function, a (possibly partial) function from models $w \in \Omega$ to their respective domains $do(w)$. (In the interests of generality, a singular term must be allowed to be empty in some models.)

It cannot be assumed in epistemic logic that individuating functions are expressed in ordinary language by singular terms of any particular linguistic category, such as proper names, in the sense that the individuating function would coincide with the meaning function of such a 'rigid designator'. This impossibility is shown by the fact that one can meaningfully ask, using a proper name, for example, 'Do you know who John is?' or 'Who is John?' The idea that there are in natural language 'rigid designators' that express individuating functions hence does not work in epistemic contexts (see Reference §3).

On the basis of these considerations, we can now formulate the additional game rules needed in epistemic first-order logic:

($\mathrm{G}.\forall$) $G((\forall x)S(x); w_0)$ begins with the choice by the opponent of an individual from the domain of w_0. If it is stipulated that a new singular term *c* has the same meaning function as the identifying function of the chosen individual, the rest of the game is as in $G(S(c); w_0)$.

Even though it seems to restrict our treatment somewhat, we can also require that the chosen individual exists in w_0, that is, that its identifying function is defined for the argument w_0.

($\mathrm{G}.\exists$) $G((\exists x)S(x); w_0)$ likewise, except that the proponent makes the choice.

In the epistemic first-order logic so far formulated, many interesting logical relationships can be expressed. However, a fully satisfactory logic of the concept of knowledge can be obtained only by extending our language in one important respect. For one thing, the interrelationship between our formal language and knowledge statements in ordinary language is made much more perspicuous by this extension.

The new element in our epistemic language is a notation for informational independence, slightly extended. Moves are sometimes made by a player in ignorance of what has happened in certain specified earlier moves. Such moves are said to be independent of the earlier ones. This idea applies naturally to our semantic games. In them an application of the rules ($\mathrm{G}.\&$), ($\mathrm{G}.\vee$), ($\mathrm{G}.\forall$) or ($\mathrm{G}.\exists$) can be informationally independent of an earlier application of one of the rules (G.K) or (G.P). Actually, in much of epistemic logic, we need to consider only the possible independence of ($\mathrm{G}.\vee$) and ($\mathrm{G}.\exists$) of (G.K).

Independence will be indicated by a slash notation, for example, in ($\vee/K$) and ($\exists x/K$). However, the possibility of moving from one model to another necessitates a specification as to what the model *w* is in relation to which a move connected with, say, ($\exists x/K$) is made. Here the obvious stipulation is that it must be made in relation to the model (world) which the rule application connected with *K* moved us away from. In brief, the slash indicates that the moves connected with *K* and with the existential quantifier $\exists x$ are made in the reverse order.

These stipulations imply that there is a difference in meaning, for example, between sentences of the following forms: $K(\forall x)S(x)$ and $(\forall x)KS(x)$. In the former, the choice of the values of *x* is between the individuals existing in an epistemic alternative chosen by the opponent. In the latter, the choice is between individuals existing in the world in which the sentence is evaluated.

It is our reliance on the notion of informational independence that forces us to use game-theoretic semantics. The reason is that the logic of informational independence cannot be handled by means of the usual Tarski-type truth-definitions.

By means of the slash notation, most of the usual types of knowledge, and most of the logical laws holding for these different types of knowledge, can be formulated. The value of a quantifier such as '($\exists x/K_b$)' is chosen independently of the epistemic alternative selected by the opponent in applying the rule (G.K). Hence the value of *x* must be the same in all the situations compatible with what *b* knows, that is, must be known to *b*. Yet this value may depend on that of a universal quantifier which depends on *K*, wherefore no linear ordering can capture the dependence relations in question. Thus we have, for instance:

(2) ' b knows whether S' $= K_b(S(\vee/K_b){\sim}S)$
(3) ' b knows whether S_1 or S_2' $= K_b(S_1(\vee/K_b)S_2)$
(4) ' b knows who satisfies the condition $S(x)$' $= K_b(\exists x/K_b)S(x)$
(5) ' b knows of everybody whether they satisfy the condition $S(x)$' $= K_b(\forall x)(S(x)(\vee/K_b){\sim}S(x))$
(6) ' b knows to whom each person bears the relation $S(x, y)$' $= K_b(\forall x)(\exists y/K_b)S(x, y)$.

Even more complex types of knowledge can be expressed in our notation. In these examples, it is assumed that the range of quantifiers consists of persons.

Of (2)-(6), the first three have equivalents in a slash-free notation, namely:

(7) $K_bS \vee K_b{\sim}S$
(8) $K_bS_1 \vee K_bS_2$
(9) $(\exists x)K_bS(x)$.

However, (5) and (6) do not have slash-free equivalents. For instance, (6) is not equivalent to:

(10) $(\forall x)(\exists y)K_bS(x, y)$.

This is seen from the following second-order equivalents to (6) and (10), respectively:

(11) $(\exists f)K_b(\forall x)S(x, f(x))$
(12) $(\exists f)(\forall x)K_bS(x, f(x))$.

This reduction of a large number of other constructions with 'knows' to the 'knows that' construction is evidence for the propositional character of knowledge.

3 Rules for quantified epistemic logic

In terms of the slash notation, deductive rules for quantified epistemic logic can be formulated.

First, the vaunted intensionality of knowledge can be understood and accounted for without postulating any special intensional entities to serve as 'objects of knowledge' (see Intensional entities). Intensionality is a matter of how meaning functions and identifying functions behave. It means that an identity which holds in one situation (model) need not hold in another one. In other words, we cannot have in our epistemic logic an unrestricted rule of the following form:

(13) $$\frac{\Gamma, S(a), a = b, S(b) \to \Delta}{\Gamma, S(a), a = b \to \Delta}$$

We can have such a rule only when *S* is required not to contain any intensional operators.

Second, rules for existential generalization and universal instantiation have to be changed. For instance, we cannot have the rule:

(14) $$\frac{\Gamma, (\forall x)S(x), S(a) \to \Delta}{\Gamma, (\forall x)S(x) \to \Delta}$$

for this inference presupposes that *a* is the same individual in all the relevant models. If *x* occurs in $S(x)$ within

the scope of only one epistemic operator, say, *K* (while $S(x)$ is in negation normal form), this rule can be restored by means of an additional premise.

(15) $$\frac{\Gamma, (\forall x)S(x), K(\exists y/K)(a = y), S(a) \rightarrow \Delta}{\Gamma, (\forall x)S(x), K(\exists y/K)(a = y) \rightarrow \Delta}$$

This modification of the usual rules is eminently natural both ‘intuitively’ and model-theoretically. If I know that *a* did something, it does not follow that I know who did it, unless I know who *a* is. At the same time, the need of the extra clause shows that in a sense the objects of knowledge are not world-bound individuals, but individuals that can be identified in several possible situations. If this is what is meant by saying that knowledge is intentional, the saying is true.

Third, rules for existential instantiation and universal generalization also have to be changed. They no longer do their whole job. We cannot have merely:

(16) $$\frac{\Gamma, S(a) \rightarrow \Delta}{\Gamma, (\exists x)S(x) \rightarrow \Delta}$$

where *a* does not occur anywhere in $S(x)$, Γ or Δ. Instead, we need a stronger rule of the form:

(17) $$\frac{\Gamma, S_0(S_1(f(y_1, y_2, \ldots))) \rightarrow \Delta}{\Gamma, S_0((\exists x)S_1(x)) \rightarrow \Delta}$$

where S_0 is in negation normal form and $(\forall y_1), (\forall y_2), \ldots$ are all the universal quantifiers within the scope of which $(\exists x)S_1(x)$ occurs in $S_0 = S_0((\exists x)S_1(x))$, and where *f* is a function symbol which does not occur anywhere in S_0, Γ or Δ. Clearly (16) can be thought of as a special case of (17). Parallel sequent rules have to be modified analogously.

Fourth, negation behaves in quantified epistemic logic in an unwonted way. For instance, the law of excluded middle no longer holds. This is almost predictable on the basis of our definitions of truth and falsity in §1 above. They imply that the law of excluded middle is a determinacy assumption, that is, that it says that one or the other player always has a winning strategy in one of our epistemic games. From game theory it is known that such determinacy assumptions are very strong, and hence likely to fail.

In general, quantified epistemic logic thus exhibits several phenomena that have no counterpart in ordinary first-order logic. In spite of the failure of the law of excluded middle, one can formulate a complete disproof procedure for epistemic logic. It can also be shown that many standard metalogical results, such as compactness, and the separation and Löwenheim-Skolem theorems, can be extended to epistemic logic.

4 Wider perspectives

The epistemic logic outlined here can be extended and applied in several different directions.

First, epistemic logics have proved relevant to such branches of computer science as artificial intelligence and database theory. A growing number of results have been reached by scientists working in this area.

Second, an interpretational rule (game rule) must be associated also with nonlogical constants of different kinds, for instance, with singular terms such as names. Applications of such rules can be independent of epistemic rules, which create distinctions between sentences such as the following:

(18) $K_b S(d)$
(19) $K_b S((d/K))$

This distinction is nothing but the so-called *de re-de dicto* distinction (see De re/de dicto). This famous distinction turns out to be another independence phenomenon and not an irreducible contrast between two kinds of knowledge nor two kinds of reference.

Third, epistemic logic is the cornerstone of the logic of knowledge-seeking developed by Jaakko Hintikka and his associates and called by them the interrogative model of inquiry (Hintikka *et al.* 1997). In fact, we obtain the rules

for such an inquiry by reversing Gentzen-type rules for epistemic logic and adding to them the following additional rule:

$$\text{(R.Q)} \quad \frac{\Gamma, S_0 \rightarrow \Delta}{\Gamma, S_0, S_1 \rightarrow \Delta}$$

where S_0 is the presupposition of any one question and S_1 the desideratum of the same question. In such interrogative inquiry, it must also be specified which questions are answerable. The applicability of (R.Q) then presupposes the answerability of the question.

Fourth, in epistemic contexts quantifiers have been shown to depend on a method of identifying individuals as members of different possible situations. Now it can be seen that individuals can be identified in two different ways. Then we have two sets of identifying functions and, corresponding to them, two pairs of quantifiers. The rules governing each of them separately are the same as have been explained. In one kind of identification, the knower uses their direct cognitive relations to objects (for example, their visual space) as a framework of identification. Such identification has been called 'perspectival'. In ordinary language, perspectival identification shows up in the form of the direct-object construction with 'knows', for example, 'Jack knows Jill', as distinguished from 'Jack knows who Jill is'. In the other, an impersonal (public) framework of identification is relied on. It can be shown that this duality is indeed realized in our actual conceptual practice with epistemic concepts. This results in an extremely important application of epistemic logic. In this application, questions concerning the interaction of the two kinds of quantifiers belong to the province of epistemology and cognitive science rather than epistemic logic.

This distinction between two kinds of identification is approximately instantiated by Bertrand Russell's distinction between knowledge by description and knowledge by acquaintance (see Knowledge by acquaintance and description), by neuroscientists' distinction between the what-system and where-system in cognition, by Endel Tulving's distinction between semantic and episodic memory, and so on. It is important to realize that these distinctions are not at bottom distinctions between two kinds of knowledge (or memory-knowledge), or between two kinds of objects within some one world, but between two kinds of principles of identification of individuals from one world to another. It is nevertheless tempting and even natural to speak of 'two kinds of objects' here. For instance, so-called phenomenological objects (including Russell's 'objects of acquaintance') are in effect individuals identified in a certain way.

Fifth, in natural language we are dealing with more than just one domain of individuals. Rather, we have at the very least a different domain corresponding to each different 'wh- question'. This distinction between different ranges of quantifiers (for that is what wh- words in effect express) is closely related to Aristotle's distinction between different categories.

Finally, a model-theoretic treatment of knowledge seems to lead to the paradox of logical omniscience, that is, to the consequence that everyone knows all the logical consequences of what they know. One natural explanation is that in their actual thinking humans articulate the possible worlds they are tacitly considering only to a certain depth. This notion of a world articulated only to a given depth can be captured by means of Rantala's (1975) notion of urn models, which hence offers a natural way out of the paradox.

Epistemic relativism

An account of what makes a system of reasoning or belief revision a good one is relativistic if it is sensitive to facts about the person or group using the system. It may then turn out that one system is best for one person or group, while a quite different system is best for another. Some of the most popular accounts of how systems of reasoning are to be assessed, including those based on reflective equilibrium and those based on the system's truth-generating capacity, appear to be relativistic. It is sometimes claimed that epistemic relativism leads to nihilism or that it severs the connection between good reasoning and true belief.

1 Relativism defined

The term 'epistemic relativism' has been used in a bewildering variety of ways. Here, we focus on an account that takes epistemic relativism to be a species of normative cognitive pluralism (see Cognitive pluralism). Normative cognitive pluralism claims that there is no unique system of reasoning (or of forming and revising beliefs) that people ought to use, because various quite different systems can all be equally good. An account of what makes a system of reasoning a good one is relativistic if the assessments of cognitive systems it offers are sensitive to facts about the person or group using the system. If systems of reasoning are evaluated in this way, then in general it will make no sense to ask whether one system is better than another: rather, we must ask whether one system is better than another for a given person or group.

2 Two relativistic accounts of cognitive assessment

Though it often goes unnoticed, some of the most popular accounts of how systems of reasoning are to be assessed are, or at least might well turn out to be, relativistic. Here, two such accounts are considered: one based on reflective equilibrium, the other based on a system's truth-generating capacity.

Nelson Goodman claimed that general principles of inference were justified by their conformity with the particular inferences we make and accept, and that our acceptance of particular inferences was justified by their accord with general inferential principles. This, he noted, looked 'flagrantly circular' but, he continued:

> this circle is a virtuous one. The point is that rules and particular inferences alike are justified by being brought into agreement with each other. A rule is amended if it yields an inference we are unwilling to accept; an inference is rejected if it violates a rule we are unwilling to amend. The process of justification is the delicate one of making mutual adjustments between rules and accepted inferences; and in the agreement achieved lies the only justification needed for either.
>
> (Goodman 1965: 64)

John Rawls (1971) introduced the term 'reflective equilibrium' to label the endpoint of the process of 'delicate … mutual adjustments' that Goodman describes.

Although Goodman did not discuss the matter, other authors have noted that there is no guarantee that everyone who uses the process will end up at the same point. If two people begin with significantly different judgments rejecting or accepting particular inferences, or with different views about which rules they are willing to amend (or both), then it seems entirely possible that they will end up with quite different sets of rules, though each set will be in reflective equilibrium. If, as Goodman insists, the process of mutual adjustment is all that is needed for rules and inferences to be justified, then these people may end up reasoning in very different ways, each of which is justified for the person who reasons in that way.

Reliabilist accounts of how to assess systems of reasoning or belief revision link the assessment to the truth-generating capacity of the system (see Reliabilism). Other things being equal, the better a system is at producing true beliefs and avoiding false one, the more highly a reliabilist will rank it. Though it is not often emphasized by reliabilists, this sort of assessment is quite sensitive to the environment in which people using the system find themselves. Thus it may well turn out that a given system of reasoning does an excellent job for one person and a very poor job for another. Imagine a pair of people who suddenly fall victim to Descartes' demon, and are from that time provided with systematically misleading or deceptive perceptual data. Suppose that one of the victims has been using cognitive processes quite like our own, and that these have done a good job in

generating truths and avoiding falsehoods, while the other victim's cognitive processes have been (by our lights) quite mad, and have produced far more falsehoods and far fewer truths. In their new demon-infested environment, however, the 'normal' system of cognitive processes will yield a growing fabric of false beliefs. The other system, by contrast, may now do a much better job at generating truths and avoiding falsehoods, since what the evil demon is doing is providing his victims with radically misleading evidence - evidence that only a lunatic would take to be evidence for what actually is the case. So on an account of cognitive evaluation in which generating truths and avoiding falsehoods plays a central role, our system would be preferable in one environment, the mad system in another. Which system a person ought to use will depend on which environment the person is in.

Invocation of evil demons to make the point might suggest that this is a very peripheral phenomenon that is hardly worth worrying about. However, the Cartesian demon case is just the very small tip of a very large iceberg. Any reliabilist evaluation of cognitive processes is going to be acutely sensitive to the cultural, technological and epistemic setting in which the processes are to function. The likelihood that one system of cognitive processes will do a better job than another at generating truth, I suspect, will depend on such factors as the existence of a system of writing, the existence and the structure of disciplinary communities, and the relation of those communities to the political and economic arrangements of the wider society. It will also often depend on the level of conceptual, mathematical, scientific and technological sophistication that has been achieved. If these conjectures are right, it follows that reliabilist accounts of cognitive or epistemic evaluation will have a certain post-Hegelian historicist flavour. There will be no one ideal method of inquiry, no cognitive system that excels in all historical settings. Rather, we can expect that the assessment of a cognitive system will vary as its historical setting varies, and that, just as with technologies (and indeed with genes), it will sometimes happen that a successful system will undermine its own success by changing the environment in such a way that competing systems will now be more successful.

3 Is epistemic relativism problematic?

Many philosophers consider epistemic relativism a dangerous or troubling doctrine. It is, however, not easy to find plausible arguments justifying this negative attitude. This section briefly sketches two lines of argument that might motivate opposition to relativism, although I do not think either argument very persuasive.

The first charge against relativism is that it is nihilistic because it simply gives up on the project of distinguishing good reasoning from bad, and embraces a sort of epistemic anarchy. From our previous discussion, however, it should be clear that the 'anything goes' slogan is a singularly inappropriate one for many relativistic accounts of cognitive assessment. Many versions of reliabilism are relativistic. But reliabilists are certainly not epistemic anarchists - quite the contrary. Reliabilism offers an extremely demanding account of cognitive evaluation. For a given cognitive agent in a given historical setting, it will typically be the case that a reliabilist evaluation will rank one system of reasoning higher than another. Rarely will it be the case that reliabilism ranks all contenders on a par.

A second complaint against relativism is that it threatens the connection between cognitive inquiry and truth. For if the epistemic relativist is right, then there may be a pair of people whose systems of reasoning are very different from one another, though each system is optimal for the person using it. We can expect that on being exposed to essentially the same data these people will sometimes end up with very different sets of beliefs. When this happens it is unlikely to be the case that both sets are true; at least one set of beliefs will be substantially mistaken. Since at least one person will end up with false beliefs, and since *ex hypothesi* they are both using optimally good cognitive systems, it can not be the case that good cognition always leads to true beliefs.

What this argument shows is that if the epistemic relativist is right, then good reasoning does not guarantee truth. But it does not show that good reasoning and truth are unconnected. If, for example, we adopt a reliabilist account of cognitive evaluation, then people who reason well will do the best job possible at producing truths and avoiding falsehoods. To expect more than this seems unreasonable.

Epistemology

Epistemology is one of the core areas of philosophy. It is concerned with the nature, sources and limits of knowledge (see Knowledge, concept of). There is a vast array of views about those topics, but one virtually universal presupposition is that knowledge is true belief, but not mere true belief (see Belief and knowledge). For example, lucky guesses or true beliefs resulting from wishful thinking are not knowledge. Thus, a central question in epistemology is: what must be added to true beliefs to convert them into knowledge?

1 The normative answers: foundationalism and coherentism

The historically dominant tradition in epistemology answers that question by claiming that it is the quality of the reasons for our beliefs that converts true beliefs into knowledge (see Epistemology, history of). When the reasons are sufficiently cogent, we have knowledge (see Rational beliefs). This is the normative tradition in epistemology (see Normative epistemology). An analogy with ethics is useful: just as an action is justified when ethical principles sanction its performance, a belief is justified when epistemic principles sanction accepting it (see Justification, epistemic; Epistemology and ethics). The second tradition in epistemology, the naturalistic tradition, does not focus on the quality of the reasons for beliefs but, rather, requires that the conditions in which beliefs are acquired typically produce true beliefs (see Internalism and externalism in epistemology; Naturalized epistemology).

Within the normative tradition, two views about the proper structure of reasons have been developed: foundationalism and coherentism (see Reasons for belief). By far, the most commonly held view is foundationalism. It holds that reasons rest on a foundational structure comprised of ‘basic’ beliefs (see Foundationalism). The foundational propositions, though justified, derive none of their justification from other propositions. (Coherentism, discussed below, denies that there are foundational propositions).

These basic beliefs can be of several types. Empiricists (such as Hume and Locke) hold that basic beliefs exhibit knowledge initially gained through the senses or introspection (see A posteriori; Empiricism; Introspection, epistemology of; Perception, epistemic issues in). Rationalists (such as Descartes, Leibniz and Spinoza) hold that at least some basic beliefs are the result of rational intuition (see A priori; Rationalism). Since not all knowledge seems to be based on sense experience, introspection or rational intuition, some epistemologists claim that some knowledge is innate (see Innate knowledge; Knowledge, tacit; Kant, I.; Plato). Still others argue that some propositions are basic in virtue of conversational contextual features. That is, some propositions are taken for granted by the appropriate epistemic community (see Contextualism, epistemological).

Foundationalists hold that epistemic principles of inference are available which allow an epistemic agent to reason from the basic propositions to the non-basic (inferred) propositions. They suggest, for example, that if a set of basic propositions is explained by some hypothesis and additional confirming evidence for the hypothesis is discovered, then the hypothesis is justified (see Inference to the best explanation). A notorious problem with this suggestion is that it is always possible to form more than one hypothesis that appears equally well confirmed by the total available data, and consequently no one hypothesis seems favoured over all its rivals (see Induction, epistemic issues in; Goodman, N.). Some epistemologists have argued that this problem can be overcome by appealing to features of the rival hypotheses beyond their explanatory power. For example, the relative simplicity of one hypothesis might be thought to provide a basis for preferring it to its rivals (see Simplicity (in scientific theories); Theoretical (epistemic) virtues).

In contrast to foundationalism, coherentism claims that every belief derives some of its justification from other beliefs (see Knowledge and justification, coherence theory of; Probability theory and epistemology; Bosanquet, B.; Bradley, F.H.). All coherentists hold that, like the poles of a tepee, beliefs are mutually reinforcing. Some coherentists, however, assign a special justificatory role to those propositions that are more difficult to dislodge because they provide more support for the other propositions and are more supported by them. The set of these special propositions overlaps the set of basic propositions specified by foundationalism.

There are some objections aimed specifically at foundationalism and others aimed specifically at coherentism. But there is one deep difficulty with both traditional normative accounts. This problem, known as the ‘Gettier

Problem' (after a famous three-page article by Edmund Gettier in 1963), can be stated succinctly as follows (see Gettier problems): suppose that a false belief can be justified (see Fallibilism), and suppose that its justificatory status can be transferred to another proposition through deduction or other principles of inference (see Deductive closure principle). Suppose further that the inferred proposition is true. If these suppositions can be true simultaneously - and that seems to be the case - the inferred proposition would be true, justified (by either foundationalist or coherentist criteria) and believed, but it clearly is not knowledge, since it was inferred from a false proposition. It is a felicitous coincidence that the truth was obtained.

One strategy for addressing the Gettier Problem remains firmly within the normative tradition. It employs the original normative intuition that it is the quality of the reasons that distinguishes knowledge from mere true belief. This is the defeasibility theory of knowledge. There are various defeasibility accounts but, generally, all of them hold that the felicitous coincidence can be avoided if the reasons which justify the belief are such that they cannot be defeated by further truths (see Knowledge, defeasibility theory of).

2 The naturalistic answers: causes of belief

There is a second general strategy for addressing the Gettier Problem that falls outside of the normative tradition and lies squarely within the naturalistic tradition (see Quine, W.V.). As the name suggests, the naturalistic tradition describes knowledge as a natural phenomenon occurring in a wide range of subjects. Adult humans may employ reasoning to arrive at some of their knowledge, but the naturalists are quick to point out that children and adult humans arrive at knowledge in ways that do not appear to involve any reasoning whatsoever. Roughly, when a true belief has the appropriate causal history, then the belief counts as knowledge (see Knowledge, causal theory of).

Suppose that I am informed by a reliable person that the temperature outside the building is warmer now than it was two hours ago. That certainly looks like a bit of knowledge gained and there could be good reasons provided for the belief. The normativists would appeal to those good reasons to account for the acquisition of knowledge. The naturalists, however, would argue that true belief resulting from testimony from a reliable source is sufficient for knowledge (see Social epistemology; Testimony).

Testimony is just one reliable way of gaining knowledge (see Reliabilism). There are other ways such as sense perception, memory and reasoning. Of course, sometimes these sources are faulty (see Memory, epistemology of). A central task of naturalized epistemology is to characterize conditions in which reliable information is obtained (see Information theory and epistemology). Thus, in some of its forms, naturalized epistemology can be seen as a branch of cognitive psychology, and the issues can be addressed by empirical investigation.

Now let us return to the Gettier Problem. Recall that it arose in response to the recognition that truth might be obtained through a felicitous coincidence. The naturalistic tradition ties together the belief and truth conditions of knowledge in a straightforward way by requiring that the means by which the true belief is produced or maintained should be reliable.

3 Scepticism

The contrast between normative and naturalized epistemology is apparent in the way in which each addresses one of the most crucial issues in epistemology, namely, scepticism (see Scepticism). Scepticism comes in many forms. In one form, the requirements for knowledge become so stringent that knowledge becomes impossible, or virtually impossible, to obtain. For example, suppose that a belief is knowledge only if it is certain, and a belief is certain only if it is beyond all logically possible doubt. Knowledge would then become a very rare commodity (see Certainty; Doubt).

Other forms of scepticism only require good, but not logically unassailable, reasoning. We have alluded to scepticism about induction. That form of scepticism illustrates the general pattern of the sceptical problem: there appear to be intuitively clear cases of the type of knowledge questioned by the sceptic, but intuitively plausible general epistemic principles appealed to by the sceptic seem to preclude that very type of knowledge.

Another example will help to clarify the general pattern of the sceptical problem. Consider the possibility that my brain is not lodged in my skull but is located in a vat and hooked up to a very powerful computer that stimulates it to have exactly the experiences, memories and thoughts that I am now having. Call it the 'sceptical hypothesis'.

That hypothetical situation is clearly incompatible with the way I think the world is. Now, it seems to be an acceptable normative epistemic principle that if I am justified in believing that the world is the way I believe it to be (with other people, tables, governments and so on), I should have some good reasons for denying the sceptical hypothesis. But, so the argument goes, I could not have such reasons; for if the sceptical hypothesis were true, everything would appear to be just as it now does. So, there appears to be a conflict between the intuition that we have such knowledge and the intuitively appealing epistemic principle. Thus, scepticism can be seen as one instance of an interesting array of epistemic paradoxes (see Paradoxes, epistemic).

Of course, epistemologists have developed various answers to scepticism. Within the normative tradition, there are several responses available. One of them is simply to deny any epistemic principle - even if it seems initially plausible - that precludes us from having what we ordinarily think is within our ken (see Commonsensism; Chisholm, R.M.; Moore, G.E.; Reid, T.). Another response is to examine the epistemic principles carefully in an attempt to show that, properly interpreted, they do not lead to scepticism. Of course, there is always the option of simply declaring that we do not have knowledge. Whatever choice is made, some initially plausible intuitions will be sacrificed.

Within the naturalistic tradition, there appears to be an easy way to handle the sceptical worries. Possessing knowledge is not determined by whether we have good enough reasons for our beliefs but, rather, whether the processes that produced the beliefs in question are sufficiently reliable. So, if I am a brain in a vat, I do not have knowledge; and if I am not a brain in a vat (and the world is generally the way I think it is), then I do have knowledge. Nevertheless, those within the normative tradition will argue that we are obliged to withhold full assent to propositions for which we have less than adequate reasons, regardless of the causal history of the belief.

4 Recent developments in epistemology

Some recent developments in epistemology question and/or expand on some aspects of the tradition. Virtue epistemology focuses on the characteristics of the knower rather than individual beliefs or collections of beliefs (see Virtue epistemology). Roughly, the claim is that when a true belief is the result of the exercise of intellectual virtue, it is, ceteris paribus, knowledge. Thus, the virtue epistemologist can incorporate certain features of both the normative and naturalist traditions. Virtues, as opposed to vices, are good, highly prized dispositional states. The intellectual virtues, in particular, are just those deep dispositions that produce mostly true beliefs. Such an approach reintroduces some neglected areas of epistemology, for example, the connection of knowledge to wisdom and understanding (see Wisdom).

In addition, there are emerging challenges to certain presuppositions of traditional epistemology. For example, some argue that there is no set of rules for belief acquisition that are appropriate for all peoples and all situations (see Cognitive pluralism; Epistemic relativism). Others have suggested that many of the proposed conditions of good reasoning, for example ‘objectivity’ or ‘neutrality’, are not invoked in the service of gaining truths, as traditional epistemology would hold, but rather they are employed to prolong entrenched power and (at least in some cases) distort the objects of knowledge (see Feminist epistemology).

In spite of these fundamental challenges and the suggestions inherent in some forms of naturalized epistemology that the only interesting questions are empirically answerable, it is clear that epistemology remains a vigorous area of inquiry at the heart of philosophy.

Epistemology and ethics

Epistemology and ethics are both concerned with evaluations: ethics with evaluations of conduct, epistemology with evaluations of beliefs and other cognitive acts. Of considerable interest to philosophers are the ways in which the two kinds of evaluations relate to one another. Philosophers' explorations of these relations divide into two general categories: examination of potential analogies between the two fields, and attempts to identify necessary or conceptual connections between the two domains.

There is little doubt that there are at least superficial similarities between ethics and epistemology: one might say that ethics is about the appraisal of social behaviour and agents, while epistemology is about the appraisal of cognitive acts and agents. On the other hand, the widely held view that behaviour subject to moral evaluation is free and voluntary while beliefs are not, suggests one important disanalogy between the two fields.

1 Epistemic and ethical evaluations

People regularly evaluate actions as right or wrong, justified or unjustified, obligatory or prohibited, and they evaluate individuals as good or bad, virtuous or immoral. Ethics is the branch of philosophy that studies evaluations of these sorts. While ethicists do at times evaluate particular acts and agents, their concern is more typically with the general principles governing these evaluations and with the meaning and nature of the evaluations themselves. People make comparable judgments about beliefs and other cognitive acts, sometimes using the same evaluative language. They say that beliefs are justified or unjustified, that someone ought or ought not to believe a certain proposition. They also evaluate people as reasonable or unreasonable, as rational or irrational. Epistemology is the branch of philosophy that studies these sorts of evaluations of cognitive acts. Like ethicists, epistemologists are usually primarily concerned with the general principles governing epistemic evaluations and with their meaning and nature rather than with the status of particular beliefs or believers.

The evaluative nature of the central concepts of ethics and epistemology gives rise to intriguing philosophical questions. To say that an action is right, for example, seems to be to endorse or approve of the action, and it also seems to say something descriptive about the action, something that could be true or false. This suggests that there is a property or characteristic of actions, rightness, just as there are other causal, spatial or temporal properties of objects. But what sort of property is moral rightness? What connection does it have to the properties to which the natural sciences appeal? Are there universal standards of moral rightness or are standards in some sense determined individually or culturally? Can a person have an obligation to perform an action even if they do not see anything of value in the action? Analogous questions arise in epistemology. When we say that a belief is justified or that a body of evidence is good evidence for some conclusion, we seem to suggest that there is a real property - being justified - and a real relation - being good evidence for something. But what sort of property and relation are these? What connection do they have to the properties and relations of the natural sciences? Are there universal standards of justification and rationality or are standards determined individually or culturally? Can a person have good reasons to believe something even if they do not see the evidential merit of those reasons? Many philosophers have thought that there are important analogies between ethics and epistemology and that the answers to these questions in one domain may shed light on the analogous questions in the other.

2 Naturalism

There has been considerable discussion concerning the connections of ethics and epistemology to the sciences. The debate has often focused on the plausibility of doctrines known as 'naturalism'. There are at least two distinct issues taken up under this heading, one of which has received a great deal of attention from ethicists while the other has been more prominent in epistemology. The discussion of naturalism in ethics has concentrated on the plausibility of giving naturalistic definitions of ethical terms. The discussion of naturalism in epistemology has focused on the connection between empirical studies of cognition and epistemological theorizing.

Naturalistic definitions of ethical terms purport to define - or reduce - the concepts or terms of ethics to those of science. To make sense of reductionism, we first must acknowledge a distinction between two categories of properties or concepts: the evaluative properties of ethics on the one hand and the allegedly more fundamental properties of the sciences. These latter would, perhaps, include causal, structural, spatial and temporal properties.

Reductionists about ethics think that the descriptive role of moral predicates - for example 'right' - is to express moral properties - the property 'moral rightness' - and that these moral properties are simply complexes of basic scientific properties. Further, they think that it is a conceptual or philosophical job to say which complexes of natural properties moral properties reduce to. To take a simple (and not very plausible) example, an ethicist might hold that the property of being a right action is the same as the property of having the approval of the majority of people in its agent's society. This amounts to a proposed reduction of the ethical notion of a right action to a social and psychological notion of majority approval. Reductionists need not say that the entire meaning of evaluative terms is captured by these reductive definitions. They can say that there is also a prescriptive component of their meaning as well. Their contention is that their definitions bring out the core descriptive meaning of the terms, that they spell out in scientifically acceptable terms what moral properties are.

The open question argument, due to G.E. Moore, is a widely discussed objection to all proposed naturalistic definitions of ethical terms. It begins with the observation that for any proposed definitional equivalent of a term such as 'good' or 'right', it is an open (or significant) question whether things having the reductive property are always good or right. However, if the properties were identical, then it would not be an open question whether things having one would have the 'other'. Hence, no such definition is correct (see Moore, G.E. §1).

Among ethicists who reject naturalistic definitions, on the basis of the open question argument or for other reasons, there are some who contend that moral predicates do not have descriptive meaning and are instead used to express approval or disapproval or to prescribe or proscribe behaviour. On this view, known as non-cognitivism, evaluative sentences do not say anything that can be true or false. Rather, they express the speaker's attitude (moral indignation or approbation). Others contend that moral properties are natural properties of objects, though they deny the possibility of any sort of definitional reduction to the concepts of, say, physics. Some versions of this non-reductive naturalism draw on the causal theory of reference. They hold that there is a natural property of objects which is causally related to our use of words such as 'right' in some appropriate way and that an action is right just in case it has that property. There is no need to assume, however, that philosophical reflection can reveal just what this property is or that there are any other terms of our language that refer to this property and would constitute a definition of 'right'. Another view, not widely endorsed, is non-naturalism, according to which ethical properties exist and are genuine properties of objects, but they are in some sense independent of the properties studied in the sciences. It strikes many philosophers as mysterious how there could be any moral knowledge if non-naturalism is true.

One can see in the debate about naturalism in epistemology analogues of most of the views just described. There have been some attempts at naturalistic definitions of epistemic terms. An example is reliabilism, which defines 'justified belief' roughly as 'belief caused by a reliable belief-forming process'. Non-cognitivism in epistemology has found some support. For example, J.L. Austin (1946) held that to say that I know some proposition is not to describe some striking cognitive feat, nor is it to describe anything else. It is, he held, to 'give one's word' that the proposition is true. It is something like promising that the proposition is true. Notably, however, non-cognitivism in epistemology has received far less attention and support than it has in ethics.

The view that epistemic properties are not reducible to naturalistic properties is not uncommon. On this view there are fundamental epistemic facts, facts that cannot be reduced to logical or empirical facts. To say that *p* is evidence for *q* is not, according to this view, to say that *p* implies *q* or that *p* has any other logical relationship to *q*, and it is not to say that it is an empirical fact that typically, when *p* is true, *q* is also true. Thus, for example, non-naturalists might say that certain sorts of perceptual experiences simply do provide evidence for certain truths about the world or that certain data provide evidence for a particular theory. According to a similar view, defended by Chisholm (1991), epistemic concepts are all ultimately to be understood in terms of the epistemic relation 'being more reasonable than', as in 'believing *p* is more reasonable than believing *q*'. As is the case in ethics, critics of this view wonder how we could have any access to epistemological properties and relations if they are not, in some sense, complexes of natural properties.

Another element of the debate about naturalism concerns the relationship of ethics and epistemology to the sciences. A primary source for discussions of this aspect of naturalism in epistemology is Quine's 'Epistemology Naturalized' (1969). There, Quine appears to hold that traditional epistemology ought to be replaced by empirical investigation of the ways in which people form beliefs. The analogous view in ethics has scarcely received

attention from philosophers. While few epistemologists endorse Quine's replacement thesis, many agree that epistemology would benefit from closer ties to cognitive science. Epistemologists, who see epistemology as largely devoted to helping people to reason better, understandably think that their task can best be accomplished by paying attention to empirical discoveries about the ways people do reason and about their cognitive capacities. Lacking that sort of empirical information, epistemologists might recommend futile strategies that people cannot follow and attempt to correct errors that do not actually occur. The epistemological enterprise that seeks to make realistic recommendations about reasoning is in some ways comparable to efforts in applied ethics to ascertain the status of particular kinds of actions. Few would deny that empirical results have some implications for those efforts. For example, information about the deterrent effects of capital punishment surely has some bearing on its moral status. There is less clearly room for empirical input into debates about the conceptual analysis of epistemic or ethical terms. Accordingly, epistemologists and ethicists whose primary aim is to provide such analyses are less inclined to endorse naturalism (see Naturalism in ethics; Naturalized epistemology).

3 Universality, objectivity and subjectivity

A second area in which the analogies between ethics and epistemology warrant careful scrutiny concerns the universality and objectivity of the judgments under discussion. It is common to wonder whether there are standards of proper conduct or rational belief that transcend particular cultural norms, and whether there are standards that exist independently of the values and practices of any particular culture. Negative answers to these questions have long been common in ethics, and they are becoming increasingly common in epistemology. Some philosophers have tried to make use of the more developed debate in ethics about these matters to shed light on the epistemological questions (see Cognitive pluralism; Epistemic relativism).

People often wonder whether ethical evaluations are in any interesting sense 'objective'. Some of our conflicting intuitions about this possibly can be resolved by distinguishing two senses of evaluative terms. Consider a physician faced with a choice between two incompatible treatment plans for a patient with a serious disease. It seems clearly right for the physician to select the treatment plan that the evidence indicates would best serve the patient. If, however, that evidence is for some reason misleading and the other approach would in fact prove more successful, it also seems that it would be right for the physician to chose that other alternative. These judgments appear to conflict, but a plausible way out is to say that the former judgment concerns a subjective sense of 'right' and the latter concerns an objective sense of the term. More generally, we might say that the desired end of our actions is the overall well-being of those affected. An action is objectively right or good when it actually would have the best consequences among all available alternatives. It is subjectively right (for a person) when that person reasonably thinks that it would have the best consequences among the available alternatives. Some philosophers would recognize an even more radically subjective notion, according to which an action is right (for a person) provided they think, with or without good reason, that it would produce the most good. Note that the less extreme subjective notion makes at least one important ethical concept analysable in epistemic terms.

Some philosophers have suggested that there are analogous distinctions in the senses of epistemic terms, and this too may help resolve some apparent controversies in epistemology. It is unclear, however, exactly how to conceive of the distinction in the epistemic realm. One might say that the epistemic goal is true belief and that a belief is objectively epistemically justified when it achieves this goal. However, this has the plainly mistaken result that all true beliefs are objectively epistemically justified. A belief held solely on the basis of, say, wishful thinking, is not justified in any sense, even if it happens to be true. An alternative conception of the objective-subjective distinction in epistemology takes an objectively justified belief to be one held for what in fact are good reasons and a subjectively justified belief to be one held for what the believer has good reasons to think are good reasons. Again, one can say that there is an even more radically subjective notion, according to which a belief is justified provided the believer thinks, with or without good reason, that the reasons for it are good. This way of drawing the objective-subjective distinction makes even objective epistemic justification depend upon an individual's evidence or reasons, and thus it differs from objective ethical justification which has no such dependence on evidence. Hence, it seems that objective epistemic justification is perspectival or dependent upon individual factors in a way that objective ethical justification is not. In this area the analogy may be weaker than some philosophers have thought.

4 Internalism and externalism

Epistemology and ethics alike have seen extensive debate about views known as internalism and externalism. Internalists in ethics contend that the factors which determine moral rightness must be in some sense internal factors that are accessible to agents by reflection or introspection alone and that these factors must to some extent motivate agents. Externalists hold that a factor can make an action morally right for an agent even if the agent is not motivated by it or would not be motivated by it upon becoming aware of it (see Moral motivation §1). Epistemology has experienced a similar split. Internalists hold that the factors which determine epistemic justification must be internal and accessible by reflection. Perceptual experiences, memories and other beliefs would thus qualify as potential sources of justification. Further, on at least some internalist views, the relation between evidence and what it justifies is in some important sense internally accessible. Externalists, in contrast, think that factors external to, and not directly accessible to, a mind can determine what is justified (see Internalism and externalism in epistemology; Reliabilism).

5 The 'ought-implies-can' principle

An area in which the analogy between ethics and epistemology seems to break down has to do with the voluntariness of the behaviour they are about. We regularly speak of how we ought to act or believe, and of our ethical and epistemic obligations. It is natural to slide readily from the claim that an act is justified or right to the claim that it ought to be done. Similarly, it is natural to take as equivalent the statements that a belief is justified and that it ought to be held or adopted. A closer look uncovers puzzles. A widely held principle in ethics is the 'ought-implies-can' principle: a person ought to perform an action only if the person can perform the action. This principle forms the basis for the powerful inclination to think that the inability to do things excuses people from doing those things and absolves them of charges of having failed to act as they ought.

Carrying the ought-implies-can principle into epistemology is problematic. In general, our beliefs do not seem to be things over which we have any sort of direct control. At best, we can set out to expose ourselves to influences that we think are likely to lead us to form desired beliefs. If the ought-implies-can principle is true and we have only this limited sort of control over our beliefs, then it less than clear how we can be justified in believing things that we do not believe or how any actual beliefs can be unjustified. Yet, it seems clear that there are examples of both kinds. A person presented with conclusive evidence for the occurrence of some dreaded event might be psychologically incapable of believing the conclusion justified by that evidence. They are then justified in believing something but cannot believe it. Considerations of this sort lead some philosophers to conclude that the ought-implies-can principle does not hold in the epistemological realm, others to conclude that the proper subject matter of epistemic evaluation is voluntary behaviour such as evidence gathering, yet others to conclude that talk of obligation about beliefs is misguided and that epistemic justification has nothing to do with obligations. Analogues of the first and third of these responses are less common in ethics.

There are, of course, numerous other areas in which one can explore similarities and differences between ethics and epistemology. Although much of ethics has explored the evaluation of individual actions, there has also been considerable discussion of the moral virtues. Here, emphasis is placed on identifying and understanding virtuous character traits, not on identifying conditions of right and wrong action. Some epistemologists have followed suit, investigating what they call the 'epistemic virtues' and developing a brand of epistemology known as 'virtue epistemology'. Epistemic virtues might include such traits of mind as a concern for the truth, impartiality, a desire to acquire relevant evidence and so on. The least revisionary versions of virtue epistemology attempt to analyse justification and knowledge in terms of epistemically virtuous belief. More radical versions argue that epistemologists ought to focus on the study of the intellectual virtues themselves, even though their connection to knowledge and justification might be indirect. Whether further investigation of the virtues reveals close analogies or notable differences between ethics and epistemology, such investigation is likely to prove fruitful (see Virtue epistemology).

6 Conceptual connections

Some philosophers have argued that the relation between epistemology and ethics is not simply one of analogy, but rather of reducibility or interdefinability, claiming that the concepts of one domain can be defined or analysed in terms of the concepts of the other. Although the idea that the fundamental ethical concepts can be defined in epistemic terms has not received much support, it is widely held that there is an important ethical concept that can be partially defined in epistemic terms. Thus, many philosophers have held that a person is subjectively justified in

performing a particular action provided they are epistemically justified in believing that the action satisfies some appropriate ethical standard. Philosophers will differ about exactly what that standard is, depending upon their basic perspective in ethics. This sort of connection between ethics and epistemology does not help to resolve any central ethical controversies. It simply acknowledges that there is a notion of ethical justification that features in an agent's epistemic perspective.

Perhaps of greater interest to philosophers have been questions about whether epistemic concepts can be understood in terms of ethical concepts. Roderick Firth (1959) and Roderick Chisholm (1991) long debated this question, Firth arguing that the connection between epistemic justification and ethical justification is merely that of analogy, and Chisholm contending that epistemic justification is a kind of ethical justification.

The simplest possible account of epistemic justification in ethical terms holds that '*S* is justified in believing *p*' means something like 'It is morally right for *S* to believe *p*' or '*S* has a moral duty to believe *p*'. On this view, beliefs and other actions are all appraised using the same standards, whether these be consequentialist, deontological or otherwise. Epistemic appraisal is thus taken to be ethical appraisal applied to belief. This simple theory is unsatisfactory. Assuming for the sake of argument that beliefs are the sort of thing for which ethical appraisal is appropriate, there seem to be numerous cases in which ethical evaluations of beliefs depart from epistemic evaluations. Sometimes, there are decisive moral considerations against a belief that is epistemically justified. For example, it may be that one is morally justified in believing the testimony of family and friends, even when the evidence seems to go against them. Perhaps the value of optimism in the face of adversity morally justifies beliefs that go against the evidence. Examples such as these convince many that epistemic justification is not simply ethical justification applied to beliefs. Of course, the failure of the simplest analysis of epistemic justification in ethical terms does not guarantee the failure of more complex analyses. However, Firth argues that no such 'categorical' analysis of epistemic justification in ethical terms can succeed. He claims that while the epistemic fact is determined by considerations of evidential support for the belief, these considerations always leave open the moral evaluation of the belief.

Another approach to analysing epistemic concepts in ethical terms appeals to the notion of *prima facie* ethical justification. The simplest version of such an analysis says that '*S* is epistemically justified in believing *p*' means the same as '*S* has a *prima facie* moral duty to believe *p*'. This implies that if a person is epistemically justified in believing a proposition, then they have a moral duty to believe it unless some other considerations override that duty. It also implies that if a person has a *prima facie* moral duty to believe a proposition, then they are epistemically justified in believing the proposition. This latter implication opens the analysis to convincing counterexamples. One can have *prima facie* moral duties to believe propositions arising from non-epistemic sources (on the assumption that we can have duties to believe at all). In such cases, there will be the *prima facie* duty, but no epistemic justification.

In addition to efforts to define epistemic terms in ethical terms, philosophers have argued for a weaker sort of necessary connection. The best known claim along these lines is due to W.K. Clifford: 'It is wrong, always, everywhere, and for every one, to believe anything upon insufficient evidence' (1866: 346). Given two assumptions, Clifford's assertion has implications for the connection between epistemology and ethics. One is that by 'wrong' he means 'ethically wrong'. The other is that one has epistemic justification for a belief if and only if one has sufficient evidence for it. Given those assumptions, Clifford's remark implies that if a person is not epistemically justified in believing a proposition, then it is morally wrong for them to believe the proposition. What Clifford says here does not amount to a full reductive analysis, since, for one thing, it does not make a claim about the meaning of epistemic statements. Furthermore, his words do not imply that if a person has sufficient evidence for a proposition, then it is morally wrong for them to fail to believe.

Most commentators take Clifford's thesis to be too strong, for reasons such as those mentioned above. Non-epistemic factors can make belief morally wrong, even though it is supported by the evidence. A more modest thesis along the lines of Clifford's suggestion holds that if a person is justified in believing a proposition, then they have a *prima facie* moral duty to believe it. It is difficult to envisage a decisive refutation of this claim, since it only asserts the existence of a *prima facie* moral duty. Objectors must contend that epistemic justification can fail to carry any moral significance at all. Some would agree with the general line suggested by Clifford, and by Chisholm, which holds that as rational beings we have a moral duty to believe as our evidence indicates, provided

there are no stronger moral considerations imposing a conflicting obligation.

Epistemology in Islamic philosophy

Muslim philosophers agree that knowledge is possible. Knowledge is the intellect's grasp of the immaterial forms, the pure essences or universals that constitute the natures of things, and human happiness is achieved only through the intellect's grasp of such universals. They stress that for knowledge of the immaterial forms, the human intellect generally relies on the senses. Some philosophers, such as Ibn Rushd and occasionally Ibn Sina, assert that it is the material forms themselves, which the senses provide, that are grasped by the intellect after being stripped of their materiality with the help of the divine world. However, the general view as expressed by al-Farabi and Ibn Sina seems to be that the material forms only prepare the way for the reception of the immaterial forms, which are then provided by the divine world. They also state that on rare occasions the divine world simply bestows the immaterial forms on the human intellect without any help from the senses. This occurrence is known as prophecy. While all Muslim philosophers agree that grasping eternal entities ensures happiness, they differ as to whether such grasping is also necessary for eternal existence.

1 Nature of knowledge

Muslim philosophers are primarily concerned with human happiness and its attainment. Regardless of what they consider this happiness to be, all agree that the only way to attain it is through knowledge. The theory of knowledge, epistemology, has therefore been their main preoccupation and appears chiefly in their logical and psychological writings. Epistemology concerns itself primarily with the possibility, nature and sources of knowledge. Taking the possibility of knowledge for granted, Muslim philosophers focused their epistemological effort on the study of the nature and sources of knowledge. Their intellectual inquiries, beginning with logic and ending with metaphysics and in some cases mysticism, were in the main directed towards helping to understand what knowledge is and how it comes about.

Following in the footsteps of the Greek philosophers, Muslim philosophers consider knowledge to be the grasping of the immaterial forms, natures, essences or realities of things. They are agreed that the forms of things are either material (that is, existing in matter) or immaterial (existing in themselves). While the latter can be known as such, the former cannot be known unless first detached from their materiality. Once in the mind, the pure forms act as the pillars of knowledge. The mind constructs objects from these forms, and with these objects it makes judgments. Thus Muslim philosophers, like Aristotle before them, divided knowledge in the human mind into conception (*tasawwur*), apprehension of an object with no judgment, and assent (*tasdiq*), apprehension of an object with a judgment, the latter being, according to them, a mental relation of correspondence between the concept and the object for which it stands. Conceptions are the main pillars of assent; without conception, one cannot have a judgment. In itself, conception is not subject to truth and falsity, but assent is. However, it should be pointed out that *tasdiq* is a misleading term in Islamic philosophy. It is generally used in the sense of 'accepting truth or falsity', but also occasionally in the sense of 'accepting truth'. One must keep in mind, however, that when assent is said to be a form of knowledge, the word is then used, not in the broad sense to mean true or false judgment, but in the narrow sense to mean true judgment.

In Islamic philosophy, conceptions are in the main divided into the known and the unknown. The former are grasped by the mind actually, the latter potentially. Known conceptions are either self-evident (that is, objects known to normal human minds with immediacy such as 'being', 'thing' and 'necessary') or acquired (that is, objects known through mediation, such as 'triangle'). With the exception of the self-evident conceptions, conceptions are known or unknown relative to individual minds. Similarly, Muslim philosophers divided assent into the known and the unknown, and the known assent into the self-evident and the acquired. The self-evident assent is exemplified by 'the whole is greater than the part', and the acquired by 'the world is composite'. In *Kitab at-tanbih 'ala sabil as-sa'ada (The Book of Remarks Concerning the Path of Happiness)*, al-Farabi calls the self-evident objects: 'the customary, primary, well-known knowledge, which one may deny with one's tongue, but which one cannot deny with one's mind since it is impossible to think their contrary'. Of the objects of conception and assent, only the unknown ones are subject to inquiry. By reducing the number of unknown objects one can increase knowledge and provide the chance for happiness. But how does such reduction come about?

2 Sources of knowledge

In Islamic philosophy there are two theories about the manner in which the number of unknown objects is reduced. One theory stresses that this reduction is brought about by moving from known objects to unknown ones, the other that it is merely the result of direct illumination given by the divine world. The former is the upward or philosophical way, the second the downward or prophetic one. According to the former theory, movement from the known objects of conception to the unknown ones can be effected chiefly through the explanatory phrase (*al-qawl ash-sharih*). The proof (*al-burhan*) is the method for moving from the known objects of assent to the unknown ones. The explanatory phrase and proof can be either valid or invalid: the former leads to certitude, the latter to falsehood. The validity and invalidity of the explanatory phrase and proof can be determined by logic, which is a set of rules for such determination. Ibn Sina points out that logic is a necessary key to knowledge and cannot be replaced except by God's guidance, as opposed to other types of rules such as grammar for discourse (which can be replaced by a good natural mind) and metre for poetry (which can be replaced by good taste).

By distinguishing the valid from the invalid explanatory phrase and proof, logic serves a higher purpose, namely that of disclosing the natures or essences of things. It does this because conceptions reflect the realities or natures of things and are the cornerstones of the explanatory phrase and proof. Because logic deals only with expressions that correspond to conceptions, when it distinguishes the valid from the invalid it distinguishes at the same time the realities or natures of things from their opposites. Thus logic is described as the key to the knowledge of the natures of things. This knowledge is described as the key to happiness; hence the special status of logic in Islamic philosophy.

3 Logic and knowledge

We are told that because logic deals only with the known and unknown, it cannot deal with anything outside the mind. Because it is a linguistic instrument (foreign in nature to the realities of things), it cannot deal with such realities directly, whether they exist in the mind or outside it, or are external to these two realms of existence. It can only deal with the states or accidents of such realities, these states comprising links among the realities and intermediaries between the realities and language. Logic therefore deals with the states of such realities, as they exist in the mind. Such states are exemplified by 'subject' or 'predicate', 'universality' or 'particularity', 'essentiality' or 'accidentality'. In other words, logic can deal with realities only in that these realities are subjects or predicates, universal or particular, essential or accidental and so on.

Because the ultimate human objective is the understanding of the realities, essences or natures of things, and because the ultimate logical objective is the understanding of conceptions, logicians must focus on the understanding of those conceptions that lead to the understanding of the essences if they intend to serve humanity. Ibn Sina points out that since the essences are universal, such expressions are also universal in the sense of representing universal conceptions such as 'human being', not in the sense of being universal only in expression, such as 'Zayd'. A universal expression can be applied to more than one thing, as the last two examples show, but one must keep in mind Ibn Sina's distinction between these two types of universal expressions: the former represents reality, although indirectly, the latter does not. It is only the former with which the logician should be concerned (see Logic in Islamic philosophy).

Considering that the discussion of universals occupies a central place in Arabic logic, it is important to focus briefly on this subject to ensure understanding of the proper objects of the knowledge of the natures of things. Muslim philosophers divide universal expressions into five types, known together as the five predicables: genus, species, difference, property and common accident. Genus refers to the common nature of all the species that fall under it, such as 'animality' for 'human being', 'dog', 'cat' and so on. As such, it tells us what the general nature of a thing is. Species refers to the common nature of all the individuals that fall under it, such as 'human being' for 'John', 'George' and 'Dorothy'. As such, it tells us what the specific nature of a thing is. Difference refers to that which differentiates the members of the genus, such as 'rational', which differentiates the species of being human from other animal species; it tells us which thing a being is. These three universals are essential to a thing; that is, without them the essence will not be what it is. Property and common accident are accidental, in that they attach to the thing but are not part of its essence. Property refers to something that necessarily attaches to one universal only, such as 'capacity for laughter' for 'human being'. Common accident refers to a quality that attaches to more than one universal, either in an inseparable manner, such as 'black' for 'crow', or in a separable manner, such as 'black' for 'human being'. The inseparability of the common accident, however, is only in existence.

Only the first three of the above universals constitute the essences of things. If one is to understand the essence of a thing, one must first understand its genus, species and difference or differences. The understanding of these three universals takes place through the explanatory phrase and proof, of which these universals are simple elements. The explanatory phrase is either definition or description. The definition is a phrase which mirrors the essence of a thing by indicating its general and specific essential qualities, that is, its genus, species and difference; the description is like the definition except that it indicates the property instead of the difference. Thus the description does not give a complete picture of the essence of a thing as does the definition. The proof is a set of propositions, which consist of conceptions joined or separated by particles. The proof that helps in the understanding of the essences of things is that which moves from known universal judgments to an unknown universal one.

The important question that concerned Muslim philosophers is how the universals or forms that are essential to the natures of things arrive at the human mind before it has the chance to employ the explanatory phrase and proof to compose known conceptions and known judgments from them. In order to answer this question, Muslim philosophers first discussed the structure of the human soul and then the steps through which the universals pass on their way to the place of knowledge (see Soul in Islamic philosophy). As stated above, conceptions come to the mind through either the philosophical way or the prophetic way. The philosophical way requires one first to use one's external senses to grasp the universals as they exist in the external world, mixed with matter. Then the internal senses, which like the external senses are a part of the animal soul, take in these universals and purify them of matter as much as possible. The imagination is the highest internal sense, in which these universals settle until the next cognitive move. It is from this point to the next step in the philosophical journey that the details seem particularly unclear.

4 The role of the mind

All Muslim philosophers believe that above the senses there is the rational soul. This has two parts: the practical and theoretical intellects. The theoretical intellect is responsible for knowledge; the practical intellect concerns itself only with the proper management of the body through apprehension of particular things so that it can do the good and avoid the bad. All the major Muslim philosophers, beginning with al-Kindi, wrote treatises on the nature and function of the theoretical intellect, which may be referred to as the house of knowledge.

In addition to the senses and the theoretical intellect, Muslim philosophers include in their discussion of the instruments of knowledge a third factor. They teach that the divine world contains, among other things, intelligences, the lowest of which is what al-Kindi calls the First Intellect (*al-'aql al-awwal*), better known in Arabic philosophy as the 'agent intellect' (*al-'aql al-fa''al*), the name given to it by al-Farabi (§3), or 'the giver of forms' (*wahib as-suwar*). They contend that the world around us is necessary for the attainment of philosophical knowledge. Some, such as Ibn Bajja, Ibn Rushd and occasionally Ibn Sina, say that the mixed universals in the imagination that have been derived from the outside world through the senses are eventually purified completely by the light of the agent intellect, and are then reflected onto the theoretical intellect.

Al-Farabi's and Ibn Sina's general view, however, is that these imagined universals only prepare the theoretical intellect for the reception of the universals from the agent intellect that already contains them. When expressing this view, Ibn Sina states that it is not the universals in the imagination themselves that are transmitted to the theoretical intellect but their shadow, which is created when the light of the agent intellect is shed on these universals. This is similar, he says, to the shadow of an object which is reflected on the eye when sunlight is cast on that object. While the manner in which the universals in the imagination can prepare the theoretical intellect for knowledge is in general unclear, it is vaguely remarked by al-Farabi and Ibn Sina that this preparation is due to the similarity of these universals to the pure universals, and to the familiarity of the theoretical intellect with the imagined universals owing to its proximity to the imagination. In other words, the familiarity of this intellect with what resembles its proper objects prepares it for the reception of these objects from the agent intellect.

5 Philosophical and prophetic knowledge

The prophetic way is a much easier and simpler path (see Prophecy). One need not take any action to receive the divinely given universals; the only requirement seems to be the possession of a strong soul capable of receiving them. While the philosophical way moves from the imagination upward to the theoretical intellect, the prophetic way takes the reverse path, from the theoretical intellect to the imagination. For this reason, knowledge of

philosophy is knowledge of the natures of things themselves, while knowledge of prophecy is knowledge of the natures of things as wrapped up in symbols, the shadows of the imagination.

Philosophical and prophetic truth is the same, but it is attained and expressed differently. Ibn Tufayl's *Hayy Ibn Yaqzan* is the best illustration of the harmony of philosophy and religion (see Ibn Tufayl). The so-called double truth theory wrongly views these two paths to knowledge as two types of truth, thus attributing to Ibn Rushd a view foreign to Islamic philosophy. One of the most important contributions of Islamic philosophy is the attempt to reconcile Greek philosophy and Islam by accepting the philosophical and prophetic paths as leading to the same truth.

Muslim philosophers agree that knowledge in the theoretical intellect passes through stages. It moves from potentiality to actuality and from actuality to reflection on actuality, thus giving the theoretical intellect the respective names of potential intellect, actual intellect and acquired intellect. Some Muslim philosophers explain that the last is called 'acquired' because its knowledge comes to it from the outside, and so it can be said to acquire it. The acquired intellect is the highest human achievement, a holy state that conjoins the human and the divine realms by conjoining the theoretical and agent intellects.

Following in the footsteps of Alexander of Aphrodisias, al-Farabi, Ibn Bajja and Ibn Rushd believe that the theoretical intellect is potential by nature, and therefore disintegrates unless it grasps the eternal objects, the essential universals, for the known and the knower are one. Ibn Sina rejects the view that the theoretical intellect is potential by nature. He argues instead that it is eternal by nature because unless it is, it cannot grasp the eternal objects. For him, happiness is achieved by this intellect's grasping of the eternal objects, for such grasping perfects the soul. Muslim philosophers who believe that eternity is attained only through knowledge also agree with Ibn Sina that knowledge is perfection and perfection is happiness.

Epistemology, history of

Epistemology has always been concerned with issues such as the nature, extent, sources and legitimacy of knowledge. Over the course of western philosophy, philosophers have concentrated sometimes on one or two of these issues to the exclusion of the others; rarely has a philosopher addressed all of them. Some central questions are:

(1) What is knowledge - what is the correct analysis or definition of the concept of knowledge?
(2) What is the extent of our knowledge - about what sorts of things is knowledge actually held?
(3) What are the sources of knowledge - how is knowledge acquired?
(4) Is there any genuine knowledge?

Concern with the first question has predominated in philosophy since the mid-twentieth century, but it was also discussed at some length in antiquity. Attention to the second question seems to have begun with Plato, and it has continued with few interruptions to the present day. The third question was also important in antiquity, but has also been a central focus of epistemological discussion through the medieval and early modern periods. The fourth question raises the issue of scepticism, a topic which has generated interest and discussion from antiquity to the present day, though there were some periods in which sceptical worries were largely ignored.

Various attempts to answer these questions throughout the history of philosophy have invariably served to raise additional questions which are more narrow in focus. The principal one which will be treated below can be stated as:

(5) What is a justified belief - under which conditions is a belief justified?

There has been but occasional interest in this last question in the history of philosophy; however, it has been a crucial question for many philosophers in the twentieth century.

1 Ancient philosophy

The extant writings of the Presocratics primarily address issues in metaphysics and cosmology; epistemological concerns appear to arise first in Plato. In the *Meno* Plato tells the story of a slave boy who has had no formal education and in particular has never studied geometry. In a conversation with Socrates, the boy is led to answer questions about a geometrical figure and his answers turn out to be correct. The boy is led to assert that when given a square with side S, so that its area is S^2, then a square of exactly $2S^2$ is formed by taking as its side the diagonal of the original square. The boy could hardly have learned this earlier, since he is uneducated. Plato takes this example to show that the boy knew the geometrical truth all along and, more generally, that the boy's soul existed earlier in a state of knowledge. Indeed, he held that the boy's soul earlier knew all truths but had since forgotten them. What the boy was really doing in his conversation with Socrates was recollecting something he had forgotten. And this Plato takes to hold for everyone: what we think of as coming to know is really recollecting.

The soul or knower may have come into existence and so it would not have always had knowledge; or it may have always been in existence but at some time acquired its stock of knowledge; or it may have always been and always had knowledge. Plato certainly rejects the first option, especially in the *Phaedo* where he argues for the indestructibility and indefinite prior existence of the soul. He also appears to reject the second option (*Meno* 86b) so that his view would be that the soul always exists and earlier had a great deal of knowledge without having acquired this knowledge at some time.

The *Meno* also contains a distinction between true belief and knowledge (97d-98b). Knowledge, Plato says, is 'tied down' or tethered in a way that true opinion is not. This view, which seems to suggest that knowledge is justified true belief, is taken up again in the *Theaetetus*, where Plato suggests that knowledge is true belief plus an account or *logos* (201d). However, several attempts to explicate the notion of an account are rejected, and the dialogue ends inconclusively. It is not clear whether Plato rejects this account of knowledge outright, or whether he is best construed as rejecting this definition given the defective notions of an account (*Theaetetus* 210a-b).

In the *Republic*, especially in Book V, Plato addresses a version of our question pertaining to the extent of

knowledge. There he distinguishes between knowledge at one extreme and ignorance at the other, and he roughly identifies an intermediate state of opinion or belief. Each of these states of mind, Plato says, has an object. The object of knowledge is what is or exists; the object of ignorance is what does not exist; and the object of belief is some intermediate entity, often taken as what is becoming or the sensible physical world of objects and their qualities (*Republic* 508d-e; *Cratylus* 440a-d). What truly exists for Plato are unchanging Forms, and it is these which he indicates as the true objects of knowledge. Moreover, knowledge is infallible, while belief is fallible (*Republic* 477e). In thus identifying knowledge with infallibility or certainty, Plato is departing widely from the view of knowledge given in *Meno* and *Theaetetus*. And, his account of the extent of our knowledge is also severely restricted: genuine knowledge is had only of the higher realm of immutable, ideal Forms (see Certainty; Fallibilism; Plato §§11, 15).

Aristotle discusses a special form of knowledge, scientific knowledge, in the *Posterior Analytics*. A science, as Aristotle understands it, is to be thought of as a group of theorems each of which is proved in a demonstrative syllogism. In the first instance, a demonstrative syllogism in science *S* is a syllogistic argument whose premises are first principles of *S*. These first principles, in turn, must be true, primary, immediate, better known than and prior to the conclusion, which is further related to them as effect to cause (*Posterior Analytics* 71b 21-22). First principles are primary and immediate when they are not themselves demonstrable. Still, such principles are known; indeed, they are better known than the demonstrated conclusion, a contention which may mean either that they are more familiar than the conclusion, or perhaps more certain than the conclusion. The first principles are also said to be prior to the conclusions in an epistemic way: knowledge of the conclusion requires knowledge of the first principles, but not conversely (*Taylor 1990: 121*). And the first principles must explain why it is that the demonstrated conclusion is true.

The science can be extended by taking theorems proved from first principles as premises in additional demonstrative syllogisms for further conclusions. Here, too, the premises must explain the truth of the conclusion. A science will be the sum of all such theorems, demonstrated either from first principles or from already-demonstrated theorems in appropriate syllogisms. And a person who carries through all these syllogisms with relevant understanding has knowledge of all of the theorems.

The first principles, however, are also known though they are not demonstrated as theorems. On this point Aristotle gives what may be the first statement of a regress argument in favour of a kind of foundationalist position (see Foundationalism). Some might hold that even the first principles must be demonstrated if they are to be known. This would lead to an infinite regress, as these first principles would themselves be conclusions of syllogisms whose premises were other first principles which, to be known, would have to be demonstrated. To avoid the infinite regress, one would need either to allow for circular demonstration, or to agree that the first principles are not themselves known but are mere suppositions. Aristotle rejects all these options in favour of the foundationalist view in which the first principles are known even though they are not demonstrated. For him, one has an immediate, intuitive grasp of the first principles. However, his foundationalism is to be distinguished from those discussed below, because his foundations are made up of fundamental principles of special sciences.

In *De Anima*, Aristotle discusses perception and perceptual knowledge. Among perceptible objects, he distinguishes between proper and common sensibles. Common sensibles are those objects that are perceivable by more than one sense, for example, the shape of a box which can be both seen and touched. Proper sensibles are those objects that are only perceivable by one sense, for example, colour can only be seen. With respect to these proper objects, Aristotle says that one cannot be in error, or one cannot be deceived (*De Anima* 418a 9-13; 428b 17-21). So, if a person sees a white cat, they can be deceived about whether it is a cat, but not in thinking that there is white present. The same would apply to proper objects of other senses. If we then assume, as Aristotle seems to have done, that the impossibility of being deceived about *X* is sufficient for having knowledge about *X*, then we reach the conclusion that we have certain perceptual knowledge about the proper objects of each sense. What is not clear is whether Aristotle felt that one could not be mistaken about actual qualities of physical objects, such as their colours; or rather about an object's perceived qualities. Clearly the former is much less plausible than the latter (see Aristotle §6).

2 Hellenistic philosophy

The Hellenistic phase of philosophy occupies several centuries after Aristotle's death (322 BC), and is notable for

its three schools of philosophy: Epicureanism, Stoicism, and Scepticism (see Scepticism). The sceptical tradition, however, continued well into the second century AD.

The Epicurean school supported an even more thoroughgoing empiricism than we find in Aristotle, and is best known for its doctrine that all perceptions are true. In perception, Epicurus says, thin layers of atoms are emitted from external physical objects (*eídōla*) and reach our senses, which passively receive and register these *eídōla* exactly as they are. But this, *per se,* is not to have knowledge of the external causes of our experiences of *eídōla*. For that, we need to make well-grounded inferences to the existence and nature of the external objects. Epicurus, however, maintains that these inferences, doubtless causal ones, can be legitimately made, and thus that there is genuine perceptual knowledge of physical objects. The fact that these inferences may fare poorly under sceptical scrutiny is not a matter to which Epicurus paid special attention, probably because he did not think that the defeat of sceptical concerns was a necessary project within epistemology (see Epicureanism §§6-7).

The Stoic position is much less optimistic. Their central concept is that of a cognitive impression. In normal conditions a red object appears red, and one has the thought (cognitive impression) ‘This is red’. Such a cognitive impression, Stoics held, cannot fail to be true. It is not, by itself, knowledge of the red object however, because the person might not assent to this impression. One has knowledge only if one assents to a cognitive impression and this assent is firm, the sort of assent that one cannot be persuaded to withhold. Ordinary people fall short of assent of this firm sort, and so really have mere opinions about objects. Only the wise man typically engages in firm assent to only cognitive impressions; so only the wise man truly has knowledge of such objects (see Stoicism §12).

In thus restricting knowledge, the Stoic position is actually close to a sceptical doctrine. The two schools of ancient scepticism, the Academic and the Pyrrhonian, had notable differences and each had points of development over nearly five centuries, ending with Sextus Empiricus in the late second century AD. A common feature of each school, though, is an attack on claims to knowledge. For any argument towards a conclusion which goes beyond sensory appearances, sceptics maintained that an equally strong counter-argument could be given. Other sceptical arguments point to the relativity of all perception, depending on changes in the percipient or in the observation conditions or perspectives, and conclude that we do not gain knowledge of external physical objects via perception. Also, if a criterion for knowledge-acquisition is relied upon - such as perception or causal inductive inference as in Epicurus - then this criterion could be questioned as itself far from evidently reliable. These sceptical arguments were properly taken to lead to the suspension of belief (*epochē*), rather than to the assertion that there is no knowledge. Moreover, the Pyrrhonian sceptics noted that the ultimate goal of their arguments was a non-epistemic one, that of *ataraxía* or being undisturbed. This calm state is presumed achievable once beliefs have been suspended and one is content to carry on one’s life dealing only with appearances (see Pyrrhonism; Sextus Empiricus).

Scepticism was challenged in the early medieval period by Augustine in his *Contra Acadcemicos*, in which he dealt critically with the arguments of Cicero, the last of the great academic sceptics (see Augustine §2; Cicero). However, scepticism was not a major concern in the Middle Ages, and did not receive special philosophical attention again until the Renaissance.

3 Medieval philosophy

Medieval philosophy is concerned primarily with issues in metaphysics, logic and natural theology, less with epistemological topics. Aquinas and Ockham, however, were two thinkers for whom epistemological questions were of great interest and importance.

Aquinas closely followed Aristotle on many points, including Aristotle’s account of scientific knowledge (see §1 above). Thus, *scientia* or genuine scientific knowledge is restricted to propositions proved in demonstrative syllogisms whose premises are themselves known. And, as in Aristotle, Aquinas holds that this account of *scientia* requires as premises in some demonstrative syllogisms, first principles that are known *per se*, immediately and without inference. That there must be such first principles is shown by the fact that otherwise one is faced with either an infinite regress of items of knowledge or with circularity. The former is ruled out because nobody can achieve an infinite number of inferential steps; and circularity, wherein one knows *p* on the basis of *q* and knows *q* on the basis of *p,* is dismissed because it allows that a single proposition, *p*, can both be and not be epistemically prior to *q*. For both Aquinas and Aristotle, the premises of a demonstrative syllogism are epistemically prior to

their conclusions in the sense that one cannot know the conclusion without first knowing the premises, though not vice versa.

First principles of demonstrative syllogisms, for Aquinas, are necessary truths, propositions in which there is a necessary connection between the predicate and subject concepts. To grasp or know a first principle, then, requires that one grasp this necessary connection. To achieve this, one must first possess the general concepts expressed by the subject and predicate terms. Accordingly, Aquinas gives an account of how we may acquire such concepts. To do this, one must abstract the intelligible species or forms of objects from the sense impressions received in perception of them. Ultimately, then, knowledge of the first principles depends on perception, though it is not epistemically based on perception.

William of Ockham makes an interesting break with Aquinas' conception of knowledge. Part of the break concerns the fact that Ockham allows for knowledge of contingent truths, as opposed to restricting knowledge to necessary truths. Another difference concerns perception. Aquinas held that, in perception, one has an experience of an image or phantasm from which by some cognitive mechanism (called an agent intellect) one abstracts an intelligible species or form of the perceived object. By means of this abstracted item one knows some universal aspect of the perceived object (see Aquinas, T. §11). Ockham disagrees with a number of these points. For him, in perception of an external physical object, there is no intermediary such as a phantasm or sensible species. Instead, the object is itself perceived directly, an experience which Ockham regards as an intuitive cognition. In this respect, Ockham's account is close to that of perceptual direct realism (see Perception, epistemic issues in). But he also holds epistemic direct realism, because he argues that the direct visual awareness of the external object suffices for one to acquire immediate and certain knowledge of the existence of the object and of some of its qualities. In this regard, one is 'knowing the singular' rather than something universal; and the proposition one comes to know in perception is a contingent truth. So, in perceiving a red box, one might come to know that there is a red box before one.

Sceptical worries could intrude, even here. One might see a red box and still be mistaken in one's resulting belief. One might think, therefore, that forming the belief as a result of a red-box visual experience does not suffice for knowledge. Ockham is aware of this objection, but he has a two-part answer to it. First, he notes that the mere possibility of mistaken belief does not rule out knowledge. He also notes that aligning the concept of certainty with the impossibility of mistaken belief is itself an error. Certainty, he says, requires only the absence of actual doubt or grounds for doubt. Certainty of this weaker sort, he holds, is all that is needed for knowledge (see William of Ockham §§4-5).

This is a decisive break with earlier views, both with respect to the concept of certainty and with respect to its relation to the concept of knowledge. But, with one or two notable exceptions, these ideas were not taken up by many writers until much later.

4 Modern philosophy: Descartes

It is customary to begin the story of modern philosophy with Descartes, but we need to start a little farther back with a discussion of scepticism. We have noted that ancient scepticism was hardly known during the Middle Ages. In the sixteenth century, however, the old sceptical texts of Cicero were re-published and works by Sextus Empiricus were translated into Latin and thus made available to scholars. These texts and their arguments became very important to those on both sides of disputes over the legitimacy and extent of religious knowledge, an issue given great currency by the Reformation and the Counter-Reformation. Under the direct influence of Sextus Empiricus, Montaigne published his *Apology for Raimond Sebond* (1576) in which he set forth sceptical arguments and recommended suspension of belief on practically all topics. His disciple, Pierre Charron, popularized sceptical doctrines even further. This sceptical climate was well known to Descartes in the first half of the seventeenth century. Still later, Pierre Bayle's *Dictionary*, which contained a number of sceptical entries, was to have a great deal of influence on Berkeley and Hume (see Bayle, P.).

Descartes was thoroughly aware of the sceptical writings and debates of his time, and of the development of sceptical literature since Montaigne. But Descartes himself was no sceptic; on the contrary, he set out to defeat scepticism on its own terms, that is, by finding some knowledge which is completely certain and thus immune to sceptical criticism.

To accomplish this, Descartes used the method of doubt, a method wherein a proposition is considered false provided there is even the slightest possible ground for doubting it. Whole classes of propositions would then be excluded as not known: everything which one believes on the basis of the senses is dubitable by this criterion, and so is not knowledge. The many propositions of science also qualify as dubitable, and so are not items of knowledge. Indeed, it is possible, Descartes reasons, that an evil demon systematically deceives us all, even with respect to the necessary truths of mathematics. If such a demon is even possible, then there is at least the possibility of grounds for doubt, and so virtually nothing would qualify as knowledge.

Descartes contends, however, that such an evil demon cannot deceive him in one case, namely when he thinks in any way. Even when the thinking in which he engages is a case of doubting, whenever Descartes thinks he must exist, and thus he affirms as certain '*Cogito, ergo sum*' - I think, therefore I exist. This is an item about which he cannot be deceived, and it is thus for Descartes indubitable or certain, and assuredly a case of knowledge.

Descartes' epistemological project then becomes one of seeing whether any other genuine certain knowledge can be derived from this very slender base. He finds first a criterion for certainty: those thoughts or ideas which are clear and distinct are also true. In fact, he says that clarity and distinctness of a thought or idea suffices to assure him of its truth. Using this criterion together with his certain knowledge that he exists, Descartes constructs a complex causal argument for the existence of God. The clarity and distinctness of the thoughts that God is not a deceiver and that God would not allow wholesale deception is then put to work to try to derive propositions formerly excluded as dubitable by the method. Especially important here are propositions concerning the existence of external physical objects.

Descartes' project is thus a foundationalist one of an austere sort. For him, the foundations are restricted to the propositions that he himself exists, that he has certain ideas, and that God exists. From these, utilizing the criterion of clarity and distinctness, the foundations can be augmented to include propositions about immediately experienced sensations. However, derivations of other propositions from these foundational ones have to be restricted to deductions that themselves can be seen to be clear and distinct. If the derivations were inductive, then grounds for doubting the conclusions would be possible. And even if the derivations were deductive, if one did not see that they were validly made from individually indubitable premises, once again the possibility of grounds for doubting the conclusions would arise. Only if the possibility of such grounds are eliminated can these derived conclusions count as items of knowledge.

Descartes, thus, perpetuates and even emphasizes the close conceptual connection between knowledge and the strictest sort of certainty (see Certainty). He also gives currency to the problem of the external world, that is, the problem of deriving propositions concerning external physical objects from foundational propositions made up mostly of propositions concerning sensations. Of course, Descartes has propositions about a non-deceiving God in his foundations, unlike later writers who grappled with this problem. So armed, Descartes claims in the sixth Meditation that he can derive the general claims that there are external physical objects and that they have at most the so-called primary qualities. But even if these claims count as items of knowledge, so that to some extent scepticism is vanquished, it does not seem that Descartes secures knowledge of individual propositions about physical objects and their qualities. For he concedes that, with respect to these, error is possible in the best of circumstances, even with God's help (Williams 1978: 234, 249ff) (see Descartes, R. §§3-5).

5 Modern philosophy: Spinoza and Leibniz

It is customary to classify Spinoza and Leibniz along with Descartes as rationalists. In epistemology, rationalism is the view which stresses the role of reason in the acquisition of knowledge, and correspondingly downplays the role of experience or observation. A limiting case of rationalism, then, would be a position which held that only reason is operative in knowledge acquisition. It is perhaps Spinoza who comes closest to a rationalist position of this sort (see Rationalism).

For Spinoza, a true idea is one which must agree with its object (*Ethics* I: Ax.6). An adequate idea is one which, considered by itself, has an internal sign or intrinsic mark of a true idea (*Ethics* II: Def.4). Having an adequate idea, then, suffices to recognize it as true. There is no need of a clarity-and-distinctness criterion for determining which ideas are true. In this respect, Spinoza differs sharply from Descartes.

Spinoza distinguishes three levels of knowledge. The first is that which we receive in sense perception or from

what he calls ‘signs’, as when the sight of some printed words causes one to remember something. First-level knowledge is not strictly knowledge, however, but rather opinion or imagination. Second-level knowledge or reason (*ratio*) is knowledge of the properties of objects and of relations between properties. Third-level knowledge is intuitive science, which Spinoza says ‘advances from an adequate idea of the formal essence of certain attributes of God to the adequate knowledge of the essence of things’ (*Ethics* II: pr.XL, schol. 2). Third-level knowledge proceeds from one thing to another in the sense that a person who has an adequate idea of the formal essence of one of God’s attributes may logically infer to adequate knowledge of the essence of things.

Knowledge is adequate when one may logically infer, merely from having an adequate idea of *x*, to some general truth about *x* (second level), or to some truth about *x*’s effects (third level). Thus, on the second level, from an adequate idea of body one may infer that all bodies are capable of motion, and thus knowledge of this proposition is adequate. And from the adequate idea of the essence of a divine attribute, one may infer to the essence or nature of objects, and thus the proposition concerning the essence of the objects is adequately known.

Spinoza certainly thinks we have adequate ideas, and so have adequate knowledge (*Ethics* II: pr.XXXIV). And he holds that the propositions known at the second and third levels are necessarily true (*Ethics* II: pr.XLI). So, it looks very much as if Spinoza is committed to the view that second- and third-level knowledge is a priori, that is, knowledge that need not rely on experience, and to this degree he would qualify as a rationalist (see Spinoza, B. de §§7-8).

Leibniz, the other great philosopher usually classified as a rationalist, did not develop a systematic view in epistemology. His classification as a rationalist is no doubt tied to two important strands of his thought. For simple subject-predicate propositions, fundamental for Leibniz, he proposed the predicate-in-notion principle. This is the thesis that the concept of the predicate in such a proposition is contained in the concept of the subject. It seems as though this principle implies that all subject-predicate propositions are necessarily true. For the conceptual-containment doctrine amounts to the claim that such propositions are true in virtue of their meanings or are conceptually true, and this would make them necessarily true. This has the twofold result that all truth is necessary truth, given that subject-predicate propositions are fundamental; and, that all knowledge is or can be a priori, the latter on the assumption that if a proposition is a necessary truth, then it is a priori knowable. If Leibniz held these views, his status as a rationalist is secure.

Leibniz strove to ward off these consequences, however, by an account of analysis. He held that in a necessary proposition, the concept-containment feature allows for the proposition to be analysed or reduced to an identity proposition in a finite number of steps. Contingent truths, however, cannot be so analysed, despite the concept-containment thesis. Instead, in an infinite number of steps of analysis, such propositions would converge on an identity proposition. (Sometimes Leibniz suggests that such propositions can be analysed into identity propositions by God.) So, not all truths are necessary, and thus neither is all knowledge a priori.

There is a strong rationalist side to Leibniz, however, which emerges in the second strand of his thought, namely, his defence of innate truths. In a dispute with Locke, Leibniz contended that there are numerous innate concepts and principles in pure mathematics, logic, metaphysics and ethics. These innate truths are all necessary truths, and they are all knowable a priori. The senses, Leibniz says, merely function as the occasions by and on which these truths are brought to attention (see Leibniz, G.W. §§8-9).

6 Modern philosophy: Locke and Berkeley

Locke provides a strong empiricist contrast to both Spinoza and Leibniz. For Locke, the fundamental items of all cognitions are ideas, which divide into those of sensation and those of reflection. The former are acquired in perception, the latter in introspective attention to the contents and workings of one’s own mind. Perception and reflection, for Locke, make up experience, and the fundamental empiricist thesis is that all ideas and all knowledge derive from experience. It follows from empiricism so construed that no ideas are innate. For Locke, the mind is a ‘blank tablet’ at birth, and it is only by experience that it acquires its stock of ideas.

Locke defines knowledge as the perception of the agreement or disagreement of two ideas (1689: IV, I, 1 and 5). This definition has the immediate effect of restricting all knowledge to ideas, something Locke recognizes and appears to accept (1689: IV, II, 1). It also seems to have the effect of restricting knowledge to relations between ideas. The definition and the restriction accord well with most of what Locke says about knowledge.

Intuitive knowledge is the perception of the agreement or disagreement between two ideas 'immediately by themselves, without the intervention of any other' (Locke (1689): IV, II, 1). Perception that white is not the same as black, for example, is immediate and requires no intermediate idea between those of white and black. Intuitive knowledge, for Locke, is the most certain: it is both irresistible and infallible.

Locke seems to desert his definition of knowledge in three important cases, however, and in two of these cases intuitive knowledge is at issue. One has, for instance, intuitive knowledge of individual ideas, as when one knows that some pain is very sharp (Locke 1689: IV, II, 1). Locke also maintains that one has intuitive knowledge of oneself. In such a case, even if an idea of reflection is had, self-knowledge is not a perception of an agreement or disagreement of two ideas. Moreover, it is knowledge about the self, which is not an idea or group of ideas. In this case, Locke departs not merely from his definition, but also from his explicit claim about the extent of our knowledge.

Demonstrative knowledge, for Locke, requires that each step in the demonstration be intuitively known, and that the relation between the premises and the conclusion also be intuitively known. Meeting these constraints on demonstrative knowledge assures that it is virtually as certain as intuitive knowledge. But meeting these constraints is not easy, especially in long demonstrations where one must keep in mind inferences made earlier. In such cases, Locke indicates, one's degree of certainty with respect to the conclusion will drop and one will not have demonstrative knowledge properly speaking.

Locke's account of sensitive knowledge marks a third point at which he seems to depart from his official definition of knowledge and the restriction of knowledge to our ideas. Sensitive knowledge is knowledge of the existence of external physical objects. It is not as certain as intuitive or demonstrative knowledge, yet it is still knowledge. And Locke clearly thinks that we have such knowledge, at least in those cases when an external physical object is actually present to one's senses (1689: IV, III, 5). Locke conceives of sensitive knowledge of presently perceived physical objects as inferential knowledge. From knowledge of presently experienced ideas one infers that there is an external physical object present as the cause of those ideas. Locke is untroubled by sceptical worries over whether such inferences can be legitimately made.

The distinction between intuitive and certain knowledge of ideas, and sensitive knowledge of physical objects, with the latter knowledge inductively based on the former, is indicative of Locke's foundationalist position. It differs from that proposed by Descartes, however, in two important ways. First, the propositions making up the foundations are different. For Locke, these are confined to propositions about individually experienced ideas, or to propositions describing a perceived agreement or disagreement between ideas. Thus, Locke's commitment to empiricism dictates what the foundations shall be. Another difference comes in the inferences from the foundational propositions which Locke finds acceptable. He allows for both deductive and inductive inferences, whereas for Descartes permissible inferences may only be deductive. Locke thus marks a liberalization of the foundationalist strictures imposed by Descartes (see Locke, J. §§2-3).

Berkeley was critical of Locke's account of knowledge of physical objects, as was Hume (though, unlike Berkeley, Hume did not mention Locke by name). Locke notes that inductive inferences from currently experienced ideas to physical objects will succeed only when there is a conformity between the ideas and the physical object (1689: IV, IV, 3). Ideas, that is, have to represent the physical objects in some way. Berkeley denies that ideas can serve this role. An idea, he says, can only be like or similar to another idea, not a physical object. Moreover, even allowing for this similarity, the needed inductive inferences depend on and so require that one establish that some ideas do adequately represent objects. To accomplish this, Berkeley argues, one must be in a position to compare the ideas and the physical object. However, as Berkeley notes, this is a position one cannot occupy given Locke's account of perception, which restricts immediate perception to ideas, and so never allows for immediate perception of physical objects. Locke's overall theory, according to Berkeley, really leads to scepticism about physical objects.

To avoid this, Locke could drop the demand that currently experienced ideas conform to or represent objects. Berkeley suggests that this manoeuvre is no help because Locke's theory still requires inductive inferences from the ideas to the physical objects. He notes that the inferences at issue would be explanatory - the supposition that there are physical objects present causally explains the ideas one experiences - but denies their cogency (Berkeley

1710: 19-20, 53). A simpler and thus better explanation of our ideas, Berkeley argues, would be the supposition that they are caused by a single powerful being such as God.

Locke's empiricist version of foundationalism is often attributed to Berkeley. However, Berkeley seems to reject such a theory in favour of a foundationalism both more expansive and more modest. It is more expansive because Berkeley allows that we have immediate and certain knowledge of physical object propositions as well as propositions about currently experienced ideas. Hence, while Berkeley accepts an empiricist version of foundationalism, the propositions he is willing to count as foundational include many more than are countenanced on Locke's theory. Berkeley's theory is more modest in regard to the concept of certainty. For him, a proposition is certain provided that one has no actual grounds for doubting it. It is not further required that mistaken belief is logically impossible. In this way, Berkeley is able to contend that physical object propositions are certain, and he can avail himself of a much more modest criterion of what is to count as a foundational proposition. On this point, Berkeley lines up with Ockham (see §3 above), and with certain twentieth century philosophers (see §8 below).

Berkeley also aimed to refute scepticism regarding the external world. He argues that this may be achieved provided one can find a way to allow for the immediate perception of physical objects. His thought is that if we perceive physical objects immediately, then we also have immediate and certain knowledge of them. He claims that these results are all achieved by abandoning realism regarding physical objects, and embracing instead a thesis which entails that objects exist if and only if they are perceived. Thus, he defends the phenomenalist thesis that a physical object is identical to a collection of ideas (see Phenomenalism). Objects which are collections are immediately perceivable so long as one immediately perceives some of their constituent members. So, the phenomenalist thesis regarding objects allows Berkeley to defend the view that physical objects are immediately perceivable, and hence to argue for the claimed refutation of scepticism and a more expansive foundationalism. In these respects, Berkeley claims, he is merely defending the views of common sense (see Berkeley, G. §§5-9).

7 Modern philosophy: from Hume to Peirce

Both Locke and Berkeley accept the theory that in every perceptual experience, one is immediately aware of at least one idea. Hume follows them in this, but he distinguishes between impressions, which are our more lively and original perceptions, and ideas, which are less lively. In seeing a red cup, one experiences a red impression (or perhaps an impression of red), while in remembering the cup one attends to an idea of the red cup. Hume's fundamental principle is that all ideas are derived from impressions, and in this regard he is a thorough-going empiricist about concepts (ideas).

He also seems to accept epistemic empiricism, at least in the sense that a proposition about an object not currently present to one's senses would count as knowledge only if that proposition were derivable from propositions about currently experienced impressions. Hume denies that physical-object propositions can be deduced from propositions about impressions. He also notes that inductive inference is not something that can be given a non-circular justification. Hence, the inductive inferences from impression propositions to physical-object propositions are not justified, and so scepticism regarding physical objects results.

Hume does note, however, that nature or our psychological make-up does not allow us actually to accept scepticism, or to refrain from making inductive inferences, especially causal ones. He may mean that the fact that we are built in such a way, psychologically, that we make inductive inferences beyond our impressions to beliefs about physical objects itself constitutes being justified in having these beliefs and making these inferences. If so, then Hume is an early externalist about justification and knowledge (see Internalism and externalism in epistemology). Or, he may mean that we can only describe the beliefs we have and the inferences we make; questions about the justification of these inferences and whether the beliefs count as knowledge cannot be settled. In that case, Hume accepts the sceptical results noted above (see Hume, D. §2).

Two very important critics of what they regarded as Humean scepticism were Reid and Kant. Reid argued that Hume's scepticism was generated by acceptance of the theory of ideas (impressions), arguing that no philosopher had ever given any good reason for accepting this theory, and that it gives a mistaken account of perception in any case. The correct account, for Reid, is a complex version of direct realism in which we gain immediate and certain knowledge of physical objects. The beliefs we gain in direct perception of objects are typically irresistible, and it is a first principle for Reid, a matter of common sense, that perception is reliable and so such beliefs are justified and

constitute knowledge (see Reid, T. §§1, 7).

Hume's scepticism did not extend to what he called 'relations of ideas'. These included the necessary truths of mathematics, and of these Hume allowed we can have a priori knowledge (1748: IV, 1). It was only with respect to some statements of matters of fact that Hume was sceptical. For Kant, relations of ideas are analytic statements, while matters of fact are synthetic (see A priori; A posteriori; Analyticity). He felt that there was a third category, however, which Hume had missed, namely synthetic a priori propositions. These are necessary truths in which the meanings of the predicate terms are not contained in the meanings of their subject terms; hence, they are synthetic. But Kant argued that the necessary truths of geometry and arithmetic are synthetic a priori, as are some very general principles of science, and these can all be known a priori. He argues that the a priori concepts he calls categories genuinely apply to objects we experience, and that our experience actually is objective in the sense that it is of real physical objects. Kant also held that having experience of objects suffices for having knowledge of such objects, and so scepticism regarding physical objects is incorrect (see Kant, I. §§4, 6).

Hegel's *Phenomenology of Spirit* (1807) contains an extended criticism of a doctrine often thought to be common to all empiricists, namely that there is immediate knowledge of something *given* in perception (for the classical empiricists, ideas), and that this knowing is passive in the sense that it is unmediated by concepts. This criticism, of course, would apply to any variant of empiricism, including a view which holds that physical objects and not subjective ideas are perceptually given and are objects of passive, immediate knowledge. Hegel's view is that there simply is no knowledge of this sort. Rather, all knowledge is conceptually mediated. Hegel seems to have drawn the conclusion that there is nothing at all which is given, a doctrine later given great currency in the twentieth century (see Hegel, G.W.F. §5).

Charles Peirce was another important critic of foundationalism, both empiricist and Cartesian. Against the former, Charles Peirce held that no empirical belief is certain - we can be mistaken in any empirical belief - and neither is it unrevisable - we can be reasonably motivated to give up any empirical belief in the light of new evidence. These two points make up part of Peirce's fallibilism (see Fallibilism). The Cartesian programme is criticized on the grounds that wholesale doubt is not a psychologically possible action, so that Descartes' method of securing foundations for knowledge does not succeed (see Peirce, C.S. §2).

8 Twentieth century

The empiricist tradition continued into the twentieth century in sense-datum theories of the sort found in Russell, with special attention paid to knowledge of the external physical world. It was argued that, in any perceptual experience, one is immediately aware of sense-data rather than physical objects. Sense-data are taken to be phenomenal objects having qualities such as colour and shape (see Sense-data). Immediate awareness of sense-data is acquaintance, itself a form of certain knowing, namely, knowing objects rather than propositions about objects. Propositional knowledge of objects is knowledge by description, and it is inferential, based upon acquaintance knowledge of sense-data (see Knowledge by acquaintance and description).

The needed inferences were to be underwritten by analytical phenomenalism, that is, the thesis that all physical-object sentences are analysable into, and so equivalent in meaning to, sets of sense-datum sentences. Given this equivalence, it was felt, inferences from sense-datum sentences to physical-object sentences would be secured as legitimate; thus the problem of the external world was solved.

Related theories were defended by Ayer and C.I. Lewis. Ayer dropped the notion of acquaintance. Sense-data were taken as items of immediate awareness, which typically issued in incorrigible propositional knowledge. Lewis dispensed with sense-data; he expressed the foundational sentences using ordinary idioms such as 'This seems red', but he made the same demands on these as Ayer did of sense-datum sentences. They are certain, and the basis of all other empirical knowledge. As in Russell, inferences from these were supposed sanctioned by analytical phenomenalism.

Interestingly enough, G.E. Moore also defended a sense-datum theory of perception, but did not couple it with an empiricist version of foundationalism. Rather, he defended common sense, which for him included the view that there are many particular material-object propositions which are known immediately and with certainty. For instance, Moore claimed to know, immediately and with certainty, that a certain mantelpiece was closer to his body than a specific bookcase. For Moore, knowledge of this proposition and of many other material-object

propositions need not be based on more secure knowledge of sense-data. In this regard, then, Moore’s view is more a version of epistemic direct realism than it is empiricist foundationalism (see Moore, G.E. §3).

The programme of empiricist foundationalism and analytical phenomenalism was widely criticized. The alleged incorrigibility or certain knowledge of sense-data was influentially attacked by J.L. Austin. All empirical sentences, he argued, are corrigible because in forming a belief about an object, such as is expressed by ‘This is red’, one is classifying the object as among the red things and so is relying on one’s wholly fallible memory of other comparably red items. Moreover, certainty or incorrigibility is not needed for knowledge. Many critics argued that certainty in the sense of lack of actual grounds for doubt was a more adequate analysis of this concept, and in this sense many physical-object sentences would count as certain. Analytical phenomenalism was also criticized, principally by Chisholm (see Phenomenalism §2). He showed that physical-object sentences do not entail sense-datum sentences, and hence are not equivalent to them.

Ayer and Lewis also were in rough agreement on the definition of the concept of knowledge. They held that propositional knowledge is justified true belief, an account shared by many others. Edmund Gettier (1963) argued that this definition was incorrect. His idea was that one could have a true justified belief which is not knowledge in a situation in which one reasons from some already justified beliefs to a new belief that, as it happens, is coincidentally true. Since it would then be a matter of coincidence that one’s belief was correct, it would not count as knowledge, even though it was a justified belief because it was knowingly inferred from already justified beliefs (see Gettier problems).

Gettier’s 1963 article generated a great deal of interest. While some argued that his argument was unsatisfactory, a majority assumed that he was more or less right, and many new analyses of knowledge were proposed, including many which incorporated the justified true belief analysis as a part. What has emerged as perhaps the most promising and least prone to new counterexamples is the defeasibility analysis. The key idea is that of defeated justification: where one is justified in believing a proposition *p* on the basis of evidence *e*, one’s justification is defeated when there is a true proposition *q*, such that the conjunction (*e*&*q*) does not justify *p*. The defeasibility analysis would then be that knowledge is justified, true, undefeated belief. Sophisticated versions of the defeasibility analysis have been worked out in detail by a number of authors, including Klein (1971), Lehrer (1974) and Swain (1972) (see Knowledge, defeasibility theory of).

Closely connected to the concept of knowledge is the concept of a justified belief, and a number of important theories of epistemic justification have been developed, the principal ones being foundational theories, coherence theories and reliability theories (see Justification, epistemic). We have already noted Cartesian and empiricist versions of foundationalism. In recent years some philosophers have defended modest versions of foundationalism. That is, they have defended the view that a belief would be justified if and only if either it were a basic, foundational belief, or were inferrable from basic beliefs. The modesty of the theory would then derive from the fact that basic beliefs need not be certain or incorrigible; it would suffice if the basic beliefs were to be non-inferentially justified. Beliefs are non-inferentially justified when their justification need not result from being based on or inferrable from other justified beliefs.

Many philosophers have found even modest foundationalism suspect, primarily because they have found problematic the notion of a basic, non-inferentially justified belief. Some have accordingly avoided this notion altogether, and developed coherence theories of justified belief. The core idea in all such coherence theories is that a belief is justified if and only if it is a member of a system of beliefs, and this system of beliefs is coherent. A number of different accounts of coherence have been proposed, but most favoured has been that of explanatory coherence. On such a view, some beliefs (explainees) in the coherent system are justified because they are explained by other beliefs in the system; the remaining beliefs in the system are justified in virtue of their role in explaining the explainees. A problem for these theories has been to provide a reasonable way of selecting those beliefs within the system which are to be explained (see Knowledge and justification, coherence theory of).

The most widely discussed reliabilist theory has been the reliable-process theory. The core idea here is that a belief is justified if and only if it is caused by, or causally sustained by, a reliable process. A process is reliable when it has a high truth-ratio; that is, when that process produces more true beliefs than false ones. Typical processes selected as reliable belief-forming or belief-sustaining ones are perception, memory, introspection, and inferring or reasoning.

A problem which has proved especially vexing for supporters of the reliable-process theory is that of generality. Any specific belief is produced (sustained) by a process token which is an instance of many different process types. The generality problem is essentially that of fixing how broadly to individuate the process types in question (see Reliabilism).

9 Recent issues

In a reliable-process theory cognizers may have no knowledge or awareness of the processes which cause or causally sustain their beliefs, or of the reliability of these processes. Most foundational and coherence theories, however, construe the notion of justification in such a way that a person's belief is justified only if they have some access to, or awareness of, whatever it is that serves to justify that belief. Theories with this access condition are generally thought of as internalist theories; those which dispense with the access requirement are externalist. Though widely discussed, no fully adequate resolution of the question of whether an access requirement should be imposed on a theory of justification has yet gained general acceptance (see Internalism and externalism in epistemology).

Proponents of reliable-process theories have typically tried to develop a naturalistic theory (see Naturalized epistemology). Minimally, a naturalistic epistemological theory is one in which key epistemic concepts such as knowledge and justification are analysed or explained in a form which makes use only of non-epistemic concepts. A more radical form of naturalism in epistemology, proposed by Quine, dispenses outright with the normative elements of traditional epistemology, and reconceives the subject as a part of empirical psychology (see Quine, W.V. §2). On this view, epistemology becomes a wholly descriptive discipline, one which studies how beliefs are formed, and how they are related to what we take evidence to be. Whether a minimal or more radical form of naturalized epistemology is acceptable is an open question at present.

Issues in social epistemology have also loomed large recently, as have topics in feminist epistemology. Within the former, two important questions are whether social factors play a role in determining whether a person has knowledge or justified belief, and whether non-individuals such as groups or institutions can be said to have knowledge or justified beliefs (see Social epistemology). Within feminist epistemology a leading question has been whether women acquire knowledge in ways that differ from methods of knowledge acquisition open to men. Another important issue has been whether social and cultural factors as they affect women have a bearing on what it is that women know (see Feminist epistemology).

All these recent developments in epistemology are being vigorously pursued and explored. They have served to expand and enrich the field in ways not appreciated just a few decades ago.

Williams, B. (1978) *Descartes: The Project of Pure Enquiry*, Harmondsworth: Penguin.(Outstanding and detailed treatment of all of the main ideas in Descartes' epistemology; this book is very helpful in understanding Descartes' relation to sceptical arguments.)

Epistemology, Indian schools of

Each classical Indian philosophical school classifies and defines itself with reference to a foundational text or figure, through elaboration of inherited positions, and by disputing the views of other schools. Moreover, the schools have literatures that define them in a most concrete sense, literatures that in some cases stretch across twenty centuries and comprise hundreds of texts. And without exception, every school takes a stance on the nature of knowledge and justification, if only, as with the Mādhyamika Buddhist, to attack the positions of others. A blend of epistemology, ontology or metaphysics, and, sometimes, religious or ethical teachings constitutes the view of most schools, and sometimes only very subtle shifts concerning a single issue differentiate one school's stance from another's.

Relabelling schools of Indian epistemology using terminology forged in Western traditions ('foundationalism', 'coherentism', and so on) risks skewing the priorities of classical disputants and distorting classical debates. Nevertheless, there are positions shared across some of the schools, as well as refinements of position that apparently because of merit received greater attention in classical discussions and appear to deserve it still. Given the broad context of world philosophy, selectivity cannot be free from bias stemming from a sense of reverberation with non-Indian traditions of thought. With these warnings in mind, we may proceed to examine three important approaches within classical Indian philosophy to questions of epistemology.

First, the late Yogācāra Buddhist philosophers, Dignāga (b. circa *480), Dharmakīrti (*c.*600-660) and followers, present a complex first-person approach to questions about knowledge that is constrained by an anti-metaphysical theme (found in earlier Buddhist treatises), along with a phenomenalism that grows out of a vivid sense of the real possibility of* nirvāṇa *experience as the supreme good. Their thought also exhibits an academic strand that is sensitive to non-Buddhist philosophical discussions. Second, a reliabilism identifying sources of veridical awareness is the most distinctive, and most central, approach to epistemology within classical Indian philosophy as a whole. Even the Yogācāra first-person approach gets framed in terms of reliable sources (perception and inference as* pramāṇas, *'sources of knowledge'). Philosophers of diverse allegiance make contributions to what may be called this* field *of thought (as opposed to an* approach*), since, to repeat, it is the philosophical mainstream. However, the Nyāya school (the 'Logic' school) leads in most periods. Finally, the Brahmanical school known as Mīmāṃsā ('Exegesis'), supplemented in particular by centuries of reflection under an Advaita Vedānta flag, develops what can be called an ethics of belief, namely, that we should accept what we see (for example) as real (and the propositional content of perceptual awarenesses as true), what we are told by another as true, what we infer as true, and so on, except under specific circumstances that prove a proposition false or at least draw it into question. The (Nyāya) epistemological mainstream is moved to incorporate a variation on this position; for Mīmāṃsā and Advaita, 'self-certification' (*svataḥprāmāṇya*), or the intrinsic veridicality of cognition, defines an alternative approach to questions about knowledge, awareness and a presumed obligation to believe.*

1 Buddhist pragmatism and coherentism

The most important context for the epistemology of the late Yogācārins (*c*.450 on), sometimes called the Buddhist logicians, may well be non-Buddhist developments, or views about the criteria of successful debate mutually developed in both Buddhist and non-Buddhist circles. But Buddhist soteriology ('mystical enlightenment theory'), including an anti-metaphysical attitude, appears to determine much that is distinctive in Dignāga's school's approach to epistemology. The *summum bonum* is conceived within Buddhism as an immediate experience, a state of awareness attained through concentrated meditation (*samādhi*) that is free from such disturbances as the inner voice of thought and feelings of desire. Possibly through a confusion of thought as an occurrent psychological phenomenon with conceptualization in general, Buddhist teachings of meditative practice embrace, or come to embrace, a broad anti-intellectualism, especially concerning speculative efforts of philosophy. With thought devalued, sceptical arguments found a receptive audience among Buddhist practitioners. Immediate experience, in contrast, is highly regarded. Indeed, *nirvāṇa* is immediate experience purged of distractions, in particular thought and desire. The very designation 'Yogācāra' indicates those devoted to meditation and other yogic practices. The school's focus on phenomenal presentations thus need not be taken to stem from a radically empiricist approach to questions of evidence, as in Western phenomenalism. It appears to have moorings in meditative mysticism instead.

Now sense perception in its raw immediacy and stripped (if this is possible) of all relatings to previous experiences, seems to present unique particulars; at least, this contention is made by Dignāga and other Yogācārins. The world of thought and desire is not the world of immediate experience, especially not the world of immediate experience purged of psychological defilements. The world of immediate experience is a world of ineffably interdependent and strictly unconceptualizable particulars, and perception accessible to thought and discussion is already infected with concepts, with desire-based, imaginational relatings (*kalpanās*) to other experiences. Thus the best we can do concerning generalities and concept formation (all concepts are general) and questions of warrant about the claims that purport to classify what are really unclassifiable particulars is to take a pragmatic attitude underpinned by a broad scepticism about what things are in reality. To best capture the exclusion (*apoha*) of generalities from particulars, Bessie's being a cow, for example, should be expressed as her not being a non-cow. We cognize things in accordance with what we want to do with them, and the success of actions based on our cognitions proves whether those cognitions are adequate (pragmatically true) or not.

Of course, success in action is itself made known to us through our own cognitions. The final touchstone of a cognition's veridicality is its agreement with other cognitions, or, in some formulations, lack of failure to agree. Incoherence is a cognitive dissonance that means that we hold something in error. We may well be in error about almost everything, but we do not notice it until there is a (jarring) cognitive failure of agreement. Now satisfaction of desire is also mediated by sense experience, and so some scholars have seen an implicit foundationalism (knowledge as founded in sense experiences). But Dharmakīrti at least is a coherentist in the sense that no empirical proposition is sacrosanct; any proposition can be defeated and overridden by considerations of overall coherence. Neither he, nor any Yogācārin, is a pure coherentist, however; it seems a judgment would, by virtue of being perceptual, be accorded warrant of at least a minimal sort.

The Yogācāra approach to logic appears to be broadly conventionalist, although sometimes logical principles are discussed as though they were discoveries. In the world of generalities, Bessie's not being a non-cow is always equivalent to her being a cow, for we set up our logic to have invariable rules. Again, the presentations of immediate experience do not obey logical principles. But when we worry about cognitive agreement, we reason according to rules. Dignāga concocts a table of inferential relations that is abstract and formal, unlike the treatment in Nyāya, where inference is thought to be underpinned by natural realities, by relations occurring in the world independently of us as cognizers.

Finally, much in the logical and epistemological texts of the late Yogācārins seems to grow out of a concern with criteria for proper debate, including, to be sure, what makes an argument cogent, but also criteria for appropriate procedure. In this and in many details of logic and debate theory - also even in the epistemology of sense perception - there is a lot of overlap with non-Buddhist texts. The extent to which academicism flourished among classical philosophers is underappreciated by modern scholars, who tend to look for something distinctively Buddhist in everything a Buddhist epistemologist says. But probably much or even most of Yogācāra epistemology was not considered to flow out of peculiarly Buddhist views. Dignāga, Dharmakīrti and company often seem to write simply as epistemologists, not as adherents to a Buddhist epistemological school.

2 Nyāya reliabilism

At the heart of the Nyāya ('Logic') approach to epistemology is the view that a proposition-laden awareness is to be counted veridical - for the purposes of resolving a doubt or an issue in dispute - just in case it is the result of a reliable cognitive process, *pramāṇa*. (According to Nyāya, what the veridicality of an awareness amounts to is, roughly, a reflecting of, or corresponding to, a fact; our concern, however, is not what it is for an awareness to *be* veridical, but why an awareness is to *be regarded as* veridical. This latter is a matter of reliabilism in the Logic approach, although a qualification concerning context of inquiry has to be made: see below.) Nyāya identifies four such reliable processes: perception, inference, vocabulary acquisition through an analogy drawn, and testimony. Other schools identify fewer *pramāṇas* as independent 'means of knowledge' (for example, Yogācārins accept only two, perception and inference); still others accept more (for example, Mīmāṃsā accepts six) (see Knowledge, Indian views of).

Logic's reliabilism is a causal theory of knowing; it is articulated in the *Nyāyasūtra* (*c.* AD 150; although it did not reach its present form until about 400) and developed in commentaries and extra-commentarial literature stretching into modern times. We rely on our cognition to get what we want, and both our getting it and knowing it are

natural, causal processes.

Logic philosophers may also be said to be empiricists in the precise sense of viewing perception as our principal cognitive link with the world. It is the process generating reliable awarenesses *par excellence*. When we acquire a new piece of vocabulary through someone drawing an analogy for us, we must have already acquired analogue terms experientially, by definitions given through ostension. Testimony is reliable only if the testifier (or the first in a chain of testifiers) knows through perception (or through an inference itself perceptually based) what is being testified. Not only may the result of an inference be defeated by perception, but the crucial general rule, or 'pervasion' (*vyāpti*, wherever *F* there *G*) is established by wide perceptual experience. And, of course, through sight of a single counterinstance (an *F* but no *G*) a putative pervasion would be disproved.

An ontological realism and a fallibilism about knowledge are also important in the overall epistemological approach of the Logic school. A pervasion is held to obtain in nature, and for this reason one could, strictly speaking, be grasped from a single exhibited connection. For example, from a single instance of the sight of smoke rising from fire, the pervasion 'wherever smoke there fire' could be grasped; or, from viewing a horse and a cow, one can know that a horse is not a cow and - to express the pervasion known, here a negative one - 'whatever is a cow is not a horse, and conversely'. Repeated experience of the connection (along with no experience of the presence of an *F* without a *G*) increases one's confidence. Perception, inference and the rest are natural causal process, and generally reliable, but on a particular occasion there may be no way of knowing whether we are right or wrong. Knowledge is a factual matter, and we may well not know that we know something or other when in fact we do know it. That is to say, a lower-order fact may be being cognized ('That is a pot' as known), without one's becoming aware that one knows ('I am knowing "That is a pot"' as itself not known), just as there are plenty of other types of fact of which we are unaware. With the exception of apperception (see Awareness in Indian thought §3), certification, according to Nyāya, is a process external to the knowledge episode that is certified - a position giving rise to disputes between Logicians and Exegetes (see §3).

The difference between inquiry about a cognition's source and ultimate certification appears to be a matter of context. Most generally, certification depends on the success of action undertaken on the basis of a (claim-laden) cognition, and sometimes we find out in action that, for example, what we thought was a veridical perception is an illusion (one cannot drink sand). But in a particular context of inquiry it may be enough to trace a cognition to its source, or to turn to the recognized sources for new information. The entire reliabilism programme of Nyāya is said to be grounded in the success of action undertaken on the basis of identified sources of knowledge. We know perception *et al.* are generally reliable by an inference based on the usual success of acts guided by perception *et al.*

3 Mīmāṃsā self-certificationalism

The Mīmāṃsā ('Exegesis') approach to epistemology emerges in the context of a challenge to religious practices and social mores now known as Hindu from, in particular, Buddhism. The teachings of the Vedas and Vedic literature were propagated by a hereditary class of priests, or Brahmans, comprising the highest of the traditional Hindu castes. Buddhism (also Jainism) rejects caste along with the Brahmanical canon. Buddhists claim that their religious teachings are founded on nothing other than experience (albeit mystical), the *nirvāṇa* experience that makes a *buddha* an expert about spiritual matters. Similar moves were made by some with regard to the Vedas. But the genius of Mīmāṃsā is to defend the Brahmanical canon by an appeal to the common practice of taking even unexamined beliefs to be correct. That the Vedas' truth is secured by a Divine Author is a position at odds with the Exegetes' polytheism and their sense of the Vedas as a moral authority superior to the gods. The Vedas are so holy and profound that no one, neither the greatest of mystics nor a god, could have composed them. The Vedas are *apauruṣeya*, 'without a person as author'. The ethics of belief that arises among Exegetes proposes more than a right to believe Vedic teachings; it proposes that we have a duty to follow Vedic injunctions to perform certain sacrifices and lead a certain form of life. Just as in perceiving an object such as a cow we require no certification extrinsic to the perception itself to act appropriately with respect to the cow, so in hearing Vedic injunctions we requires no extrinsic certification with respect to what we know we ought to do.

In classical epistemological debates, Exegetes, led by Kumārila (*c.*670) and Prabhākara (*c.*700), attend, like their rivals, to *pramāṇas*, 'knowledge sources'. The point of this focus, according to Logic philosophers, is to be able to trace a cognition or claim to a reliable source as a way of dispelling doubt and ending debate; Yogācārins turn to

coherence considerations as the test of truth and veridicality, with perception as the source responsible for an initial credibility or warrant that by agreement or disagreement with other cognitions may be strengthened or overruled. In contrast, Exegetes insist that the initial credibility of a cognition is practically absolute. Strictly speaking, no awareness is nonveridical; no cognition is absolutely wrong, but is at worst a confusion. Error can and does occur. But what is called a perceptual illusion, for example, is a confusion, or blending, of a veridical perception and a correct memory in such a way that it appears that there is a single cognition (misrepresenting the world), whereas in fact there are two. Error results from a departure from a *pramāṇa*'s normal functioning and a failure, for example, to distinguish a perception and a memory (the error of seeing mother-of-pearl as silver combines a perception of an object that is indeed there - mother-of-pearl - and a memory of silver that one has indeed previously experienced).

Exegetes promote ideas of demarcation concerning legitimate spheres of *pramāṇa* operation and causal considerations with respect to each sphere. For example, sense experience is not a legitimate source of ethical knowledge, for only an existent object can be the cause of a perception, and ethics concerns future acts.

Such reflection as this is put forth to dispel confusion, not to establish a legitimate pedigree. Inquiry concerning legitimate epistemic pedigree is not itself normally legitimate: the absolutely central thesis of self-certification does not rule out *pramāṇa* inquiry, but it allows us to take a genial, nonsceptical and inclusivist attitude (finding as we do six sources of knowledge), and to get clear about distinctions concerning what is known and how we know it.

There are different versions of self-certification (*svataḥprāmāṇya*) among Exegetes. According to Prabhākara, every veridical cognition is known to be so intrinsically, just by the occurrence of the cognition itself. Nonveridicality, however, is known extrinsically. Thus the same causal nexus that produces a veridical cognition produces knowledge of its veridicality. But when we discover an error, we discover it on extrinsic grounds. On an alternative view deriving from Kumārila, veridicality is known through a process of inference: this is the same process of inference whereby a cognition itself is known as having occurred. A cognition, which is an act, produces a feature in the object it cognizes, namely 'cognizedness', and then from apprehension of this feature, both the original cognition and its veridicality are known. (Similarly, cooking is an act that produces a feature in its object, namely 'being cooked'.) Thus on Kumārila's view, too, there is no difference between knowing a cognition as a fact and knowing it as veridical. Certification is intrinsic to a cognition's occurrence, that is, with cognitions that are veridical. With respect to knowledge of nonveridicality, extrinsic certification is required - as in Prabhākara's view.

Briefly we may note a Logic rejoinder, which is that normally there is no call to wonder about a cognition's veridicality; normally we proceed to act without wondering, and rightly without wondering, whether the cognition guiding an act is reliable. An assumption of veridicality is the epistemological default. But under circumstances that call for reflection about certification, we do not find it in the cognition itself, for that would make nonveridical cognitions impossible. Logic philosophers also hold that there is an excellence (*guṇa*) in the causal process resulting in a veridical cognition that may be said to account for its veridicality, just as there is a reliability-undercutting fault (*doṣa*) in the process resulting in a cognition that is nonveridical. Exegetes have a pretty easy time showing that this is a cumbersome conception. On the score of what cognition reveals, both schools are realist and learn and borrow from one another.

Finally, Advaita Vedāntins, generally speaking, endorse the Mīmāṃsā approach to epistemology, especially that of the Prabhākara camp. Indeed, in disputes with Logic philosophers and others, Advaitins bring out new ramifications of self-certificationalism and interesting attacks on rival positions. However, in contrast to the common-sense realism of Mīmāṃsā concerning the pots and cows of the world, Advaitins are intent upon upholding the sole reality of the self, which is identified with the Absolute, Brahman. For Advaitins, self-certificationalism proves to be an immensely important mainstay in an overall idealist polemic (see Monism, Indian §§1-2).

Equality

Equality has long been a source of political and philosophical controversy. A central question about equality is how one might link empirical or moral claims about the extent to which persons are equal to judgements about the moral acceptability or unacceptability of social inequalities, and in particular how far considerations of equality license social action to bring about greater social equality. A traditional liberal argument holds that approximate equality of human strength makes it prudent for humans to place themselves under a common political authority, thus producing a justification for equality before the law. But any generalization of this argument ignores the cases where strength is unequal and the resulting balance of power unjust. Equality of worth is a principle recognized in many philosophical traditions, but its broad acceptance leaves open many problems of interpretation. In particular, it is not clear how far the principle calls for greater equality of social conditions. Persons may derive a sense of worth from enjoying the fruits of their labour, and this will legitimately block some redistribution; certain inequalities may work to everyone's advantage; and the impartial concern of the equality principle may be at odds with the sense of ourselves as persons with specific attachments. In this context, some have wanted to soften the interpretation of equality to mean equality of opportunity or merely that inequalities should not be cumulative, although how far these moves are justified is a matter for dispute. By contrast, challenges to the equality principle from considerations of incentives, desert or difference can more easily be met.

1 The idea of equality

Nearly 2,500 years ago Aristotle remarked in *The Politics* (336-22 BC) that disputes over equality and inequality were generally behind the warfare within states. Nowadays in topics as diverse as the distribution of income and wealth, access to public services, the distribution of work and employment opportunities, the political representation of different social groups and the control of natural resources among nations, the issue of equality plays a central, but controversial, role.

The idea of equality occurs in political philosophy in three main ways. First, it has sometimes been used as a purported description of certain features of human life in society, most notably in the claim that human beings are approximately equal in strength. Second, it is used as a principle of action to the effect that persons should be treated as having equal moral worth. Third, it is used to indicate a supposedly desirable set of social conditions, for example 'one person, one vote' or a more equal distribution of income. A central issue is how far one can employ premises drawn from the first two senses of the term to evaluate social, economic and political inequalities in the third sense. In particular the question arises as to how far social inequalities are just, or at least justifiable (see Justice §5).

To speak of equality without qualification is to speak elliptically. Strictly speaking, equality is a relation that holds between objects or persons in respect of some common characteristic that they share. In most respects, human beings are unequal: they exhibit differences of height, weight, intelligence, manual dexterity, earning capacity and so on. Moreover, if society or governments were to seek to equalize some goods or resources, for example income, they would render unequal some other aspect of social relations, for example hourly rates of pay when people work for different lengths of time.

The upshot of these logical points is that the idea of equality needs to be embedded within a broader theory of politics and society in order to be given a specific content. No political theory aims at equality pure and simple. It aims instead at specific types of equality thought to be morally or socially important.

2 Equality of strength

Given the diversity of human beings, can it ever be said that all human beings are equal in any respect? In *Leviathan* (1651), Hobbes suggested that, although differing in bodily and mental capacities, human beings were equal in that it would be always possible for one person to kill another, an idea picked up by Hume in the eighteenth century and H.L.A. Hart in the twentieth.

According to this tradition, such rough equality of strength makes it prudent or rational for human beings to place themselves under a common body of rules comprising a system of mutual forbearance and agreement. Thus, despite persistent differences in wealth and status in society, equality of obligation under the law flows from

equality of strength in some hypothesized pre-legal situation. Political agents should therefore recognize a common system of authority not merely as wise but also as just.

This line of thought can be carried too far, however. For the equality of strength condition only holds under rather specific circumstances, and where it does not hold the weak are vulnerable. One intuitive idea of justice is that bargaining advantage should not be allowed to prevail where this would threaten certain fundamental interests of persons; political power will thus only be legitimate when it protects the vulnerable (see Justice §4).

3 Equality of moral worth

If we cannot establish a normatively adequate theory of politics solely on the notion of an approximate equality of strength, the idea of equality will have to be given an irreducible moral content. This introduces the second sense of the idea: namely, equality means that all persons are to be thought of as having the same moral worth and are entitled to equal respect and consideration in the treatment of their interests. Although associated with contemporary liberal political thought, both in its utilitarian and its Kantian variants (see Liberalism), this idea has also found a place in many other philosophical and religious traditions, including Jewish and Christian political thought, the Stoic tradition, and the Confucianism associated with Mencius. Currents of thought within Islam, as well as breakaway sects from Hinduism, have also advanced the idea that there is an equal moral worth of all persons. However, can any specific implications about the ordering of social relations be derived from a principle that thinkers of such varying political and philosophical persuasions have endorsed?

One issue here concerns the terms in which we spell out the implications of greater equality. Greater social equality in principle leaves open the question of what exactly is to be equalized: should it be resources, welfare or some other aspect of human life? There are sound arguments for taking any one of these possibilities as the basis of public policy.

However the issue of measurement is resolved, the central justificatory arguments for equality claim that the principle of equal moral worth places limits on what actions a state may pursue (for example, it may not privilege the interests of some at the expense of others), and that a sense of personal worth depends upon the political, social and economic institutions in which members of society participate. Yet, it is easy to see that, although in general this claim may be true, there is no simple way in which the precise nature of these connections can be ascertained.

Suppose it is allowed that people's sense of self-worth depends upon the social institutions in which they participate, so that poverty and social deprivation will undermine a person's sense of self-worth. The extent to which this assumption will license a general equalization of social and economic resources is not obvious. Thus, some libertarians have claimed that such equalization will require practices of redistribution that in effect treat the wealthy as mere means to the attainment of some social goal, in a way that is inconsistent with the respect for persons that the principle of equal worth requires (see Libertarianism §3).

In this simple form the libertarian argument does not carry much conviction, since it does not show why requiring persons to fulfil putative obligations under a principle of justice is to treat them merely as means. However, it does at least indicate that there may be constraints on the way in which the practice of redistribution is accomplished and that persons should, by and large, enjoy the fruits of their own labour.

Quite apart from these libertarian objections to the equalization of property, it has also been argued that the principle of equality it should be recognized that there may be a general advantage in some forms of social inequality. Thus, Rawls (1972) has consistently argued that it would be irrational for persons seeking to advance their own interests to prefer a more equal distribution of resources to an unequal distribution of a larger stock that left the poorest persons better off than they would be under the scheme of equality. By this argument the principle of equal moral worth is seen to coexist with permissible inequalities in the allocation of resources or welfare in society.

Further complications stem from the notion of personality itself. It may be argued that the sense of ourselves as persons derives from the special attachments that we form to other persons, or particular places and institutions. Our sense of moral worth depends therefore on subjectively meaningful attachments that limit the extent to which we can take a general impartial concern in the interests of others. For example, if all people are of equal moral worth, it would seem that large-scale international redistribution is called for to realize the principle, but such a

proposal could cut across the subjective attachments that persons form within the political communities of which they are members.

The distinctive feature of all three of these sorts of argument is that they do not simply counterpose the principle of equality to other principles of social organization, but seek instead to develop different aspects of that principle to cut the inference from equal moral worth to an equal allocation of rights and goods in society.

In response, one option is to weaken the implications of the principle of equality. For example, perhaps the principle of equal worth does not imply an equalization of rights and goods taken as a whole, but merely that there should be no discrimination in their allocation, so that relative advantages are not unfairly achieved. Similarly, it may be argued that the principle of equality merely requires that persons be given an equal opportunity to acquire unequal social and economic advantages. A particularly influential argument in this mode has been the claim that it is not social and economic inequality in itself that is objectionable, but the accumulation of social and economic inequalities across the different dimensions of social life. Related to this argument is the claim that it may be important to reduce or eliminate only certain social inequalities - in particular those that relate to access to health care or education - in order to be consistent with the principle of equal moral worth.

The most natural way to deal with this variety of interpretations is to allow that one can identify not one but a family of political positions, all of which claim to embody the principle of equal moral worth. The choice between these positions in part depends upon broader issues of social theory (for example, the extent to which one believes that inequalities in different dimensions can be kept separate) and in part depends upon the exercise of judgement (for example, the extent to which one judges that a sense of personal worth depends upon persons being able to retain the fruits of their labour as distinct from enjoying access to collectively shared rights and goods).

4 Challenges to equality

There have been a number of challenges to the moral claims of the equality principle. One familiar argument refers to the supposed disincentives to work that would be created by the practice of redistribution from the more productive to the less productive. From one point of view this can be regarded as a pragmatic question, with policy makers having to determine what the balance should be between greater productivity and greater equality. The Rawlsian difference principle, according to which inequalities should be allowed provided they raise the incomes of the least advantaged, can be interpreted here as one possible, but attractive, compromise on this question (see Rawls, J. §1).

However, the issue of incentives also raises matters of principle, since one way to avoid disincentive effects would be to adopt a scheme of taxation based not on labour but on ability. Although difficult to operate, such a scheme would in principle impose a lump-sum tax (an inherited debt) upon the more able that they would have to work to pay off. Clearly, the problem of work incentives in this case leads straight back to some of the problems of combining equality with a sense of personal attachment that were identified in the previous section.

A second principle that is often set against that of equality is the principle of merit or desert. This principle does provide a direct challenge to equality, since it requires that goods be distributed in proportion to the merits of those receiving them - with the best flute players receiving the best flutes, as Aristotle put it. However, the notion of desert is not without its own problems, and it may be argued that its application only makes sense within the context of an ongoing practice, like an orchestra with its own standards of performance, and not across society as a whole (see Desert and merit).

The final challenge to the principle of equality has come from the appeal to the notion of difference. Here the argument is that equality implies a uniformity of treatment, whereas interests in society are in fact plural. Thus, instead of basing public decision making on the principle of one person, one vote, a principle of difference would require some groups to be given a special say in certain matters of public policy, for example women a veto over changes to the law on abortion.

The extent to which the appeal to difference mounts a serious challenge to the principle of equality is a matter for dispute, however. Requiring equal consideration of the interests of all persons is compatible with recognizing that over some questions the interests of certain groups are more deeply engaged than others, as can quite easily be seen in the protection of the rights of local communities to take decisions that affect them especially. Thus, to

allow that there may be a special say for certain groups in matters of public policy may be compatible with the principle of equality, provided that the acknowledgement of the possibility is not unique to a particular group.

Despite these challenges, therefore, the principle of equality still remains as a central principle of modern political thought. But its very centrality means that continuing discussion over its exact interpretation and implications is likely for a long time to come.

Erasmus, Desiderius (*c.*1466-1536)

Although Erasmus was not a systematic philosopher, he gave a philosophical cast to many of his writings. He believed in the human capacity for self-improvement through education and in the relative preponderance of nurture over nature. Ideally, education promoted docta pietas*, a combination of piety and learning. Erasmus' political thought is dominated by his vision of universal peace and the notions of consensus and consent, which he sees as the basis of the state. At the same time he upholds the ideal of the patriarchal prince, a godlike figure to his people, but accountable to God in turn. Erasmus' epistemology is characterized by scepticism. He advocates collating arguments on both sides of a question but suspending judgment. His scepticism does not extend to articles of faith, however. He believes in absolute knowledge through revelation and reserves calculations of probability for cases that are not settled by the authority of Scripture or the doctrinal pronouncements of the Church, the conduit of divine revelation. Erasmus' pioneering efforts as a textual critic of the Bible and his call for a reformation of the Church in its head and members brought him into conflict with conservative Catholic theologians. His support for the Reformation movement was equivocal, however. He refused to endorse the radical methods of the reformers and engaged in a polemic with Luther over the question of free will. On the whole, Erasmus was more interested in the moral and spiritual than in the doctrinal aspects of the Reformation. He promoted inner piety over the observance of rites, and disparaged scholastic speculations in favour of the* philosophia Christi *taught in the gospel. The term 'Christian humanism' best describes Erasmus' philosophy, which successfully combined Christian thought with the classical tradition revived by Renaissance humanists.*

1 Life and works

Erasmus was born at Rotterdam, the illegitimate son of a priest. Orphaned at an early age, he was persuaded by his guardians to enter an Augustinian monastery. He became a canon regular and was ordained priest in 1492. In 1495 he was sent to Paris to study theology, but soon developed a strong distaste for the scholastic method taught there. When the financial help promised by his bishop did not materialize, Erasmus was obliged to support himself by tutoring well-to-do young men. In 1499 he accompanied one of his pupils to England. The visit led to important connections with future patrons (among them William Warham, Archbishop of Canterbury) and to lifelong friendships with Thomas More (see Utopianism §1) and John Colet. Over the next two decades Erasmus travelled extensively. He returned to France, visited the Low Countries, made a second journey to England, and then spent three years (1506-9) in Italy. While in Turin he obtained a Doctorate of Theology *per saltum*, that is, without fulfilling the usual academic and residence requirements. For a year he lived in Venice, doing editorial work and research for the Aldine press. On the accession of Henry VIII in 1509 he returned to England and taught Greek at Cambridge, but his hopes for royal patronage were only modestly rewarded.

By this time Erasmus had made a name for himself as the author of the homiletic *Enchiridion Militis Christiani (Handbook of the Christian Soldier)* (1503) and the witty *In Praise of Folly* (1511), both calling for spiritual renewal of church and society. In 1515 he was appointed counsellor to Prince Charles of Burgundy (later Emperor Charles V) and through the generosity of his patrons in England and the Low Countries acquired sufficient wealth to live the life of an independent scholar. He took up residence at Louvain in 1517 and with short interruptions remained there until 1521. In 1516 he published his *magnum opus*, an edition of the New Testament containing a revised text of the Vulgate faced by the Greek original (the first printed Greek text of the New Testament to reach the market). Erasmus' pioneering work as textual critic was immediately attacked by the Louvain theologians, and his move to Basle in 1521 was partly motivated by a desire to escape their hostilities. However, geographical distance did not deter Erasmus' opponents in the Low Countries. Soon opposition to his work spread to France and Spain, involving Erasmus in bitter controversy and culminating in a formal condemnation by the faculty of theology at Paris in 1531. His critics accused Erasmus of attacking the principle of divine inspiration of Scripture, undermining the traditions of the Church, and providing the underpinning for the Lutheran 'heresy'. Erasmus denied these charges. He noted that his revision of the Vulgate text was not aimed at changing the words of the inspired evangelist, but at correcting the mistakes of an incompetent translator or a careless scribe. Although he occasionally challenged the traditional interpretation of a scriptural passage, he was willing in all instances to submit his views to the verdict of the Church. While he was no doubt sympathetic to the goals of the Reformation, he disapproved of the radical methods adopted by the reformers. Trying to maintain a scholarly detachment was

difficult, however. Erasmus soon found himself attacked by both parties. Conservative theologians perceived him as Luther's inspiration; followers of Luther resented his refusal to endorse the reformer unequivocally and accused him of hypocrisy. Challenged to clarify his position, Erasmus reluctantly entered the arena against Luther with a *Discourse on Free Will* (1524). The ensuing polemic led to a breach between the two men, but failed to convince Catholic critics of the orthodoxy of Erasmus' views. The controversy over Erasmus' commitment to the Catholic faith continued after his death in 1536. In the wake of the Council of Trent which imposed strict doctrinal norms, Erasmus' works were placed on the Index of Prohibited Books.

2 Educational philosophy

Erasmus' pedagogical theories are based on the anthropological optimism that characterizes Renaissance humanism. His philosophy of education is formulated in a number of treatises, dealing with curriculum, methods and objectives. Curriculum is discussed in *De ratione studii (On the Method of Study)* (1512) and *Ratio verae theologiae (The Method of True Theology)* (1518). Erasmus rejected the traditional emphasis on logic and speculative sciences in favour of language studies, history and moral philosophy. Such a curriculum was meant not only to develop skills and train the intellect, but also to provide moral instruction and promote civic virtue. *De pueris instituendis (On the Education of Children)* (1529) is a comprehensive statement of Erasmus' views on the goals of education and the respective roles played by parent, teacher and pupil in the process of education.

Erasmus believed in the human capacity for self-improvement through education and in the relative preponderance of nurture over nature. Indeed he believed that individuals are 'made human' through education. Although Erasmus placed the customary emphasis on imitation as the principal method of learning, he defined it in a wider sense as comprising the thorough understanding of a subject. Copying models was only a first step in the learning process. This must be followed by the judicious application of skills acquired by imitation, which includes choosing elements suitable to the subject, the occasion and the parties involved. Thus Erasmus acknowledged that mastering a subject required analysis, judgment, and a process of creative appropriation. Erasmus abhorred corporal punishment and insisted that positive reinforcement and healthy competition were the most effective means of motivating the learner. In the educational process Erasmus attached a disproportionate importance to the teacher, whom he held largely responsible for the success or failure of a pupil. Apparently he considered a pupil's negative attitude to learning or inability to benefit from instruction the direct result of inadequate teaching methods. While Erasmus asserted that everyone was capable of self-improvement, he grew up with the belief that females were less likely to benefit from education than males. He tells us that he revised his views when confronted with evidence to the contrary. All of Erasmus' pronouncements on education have a Christian subtext. He believed that the student must be transformed, not only into a learned person, but a learned Christian. In his estimate, St Jerome was the perfect scholar, embodying *docta pietas*, that is, combining erudition with piety.

3 Political thought

The main source for Erasmus' political thought is his *Institutio Principis Christiani (The Education of a Christian Prince)*, published in 1516 and dedicated to the 16-year-old Prince Charles. In this essay the ruler appears as a father figure, who looks after the welfare of his people, dispenses justice and provides moral leadership. He is the representative of God and as such is owed unquestioning obedience by his people. The ruler in turn must render an account of his stewardship to God. 'He does not have the same rights over men as over cattle,' Erasmus notes. 'Government depends to a large extent on the consent of the people, which was what created kings in the first place' (*Collected Works*: vol. 27, p. 284). Consent and consultation are prominent themes in Erasmus' political writings. He saw consensus-building as an important process in the government of both state and church. Accordingly, he proposed to settle territorial conflicts among states by calling on a group of referees, and to determine dogmatic questions within the church by summoning a general council. His emphasis on consensus as a means of ensuring a correct decision also of course has epistemological implications (see §4).

The maintenance of peace and concord is another central theme of Erasmus' political writings. It is the subject of two essays, 'Dulce Bellum Inexpertis' (War is Sweet to the Inexperienced) (1515) and *Querela Pacis (The Complaint of Peace)* (1517). Erasmus' pacifism is informed by the classical ideal of *humanitas* and the Christian ideal of a universal fellowship. In *De bello Turcico (On War Against the Turks)* (1530) Erasmus accepts the concept of a 'just war' against the Ottoman Empire but disparages a military solution. Instead he promotes the idea of the Turks as a scourge of God, which calls for spiritual weapons rather than battle gear. A transfer from the

political to the theological realm is apparent also in Erasmus' image of the Christian commonwealth with Christ surrounded by clergy, princes and common people in three concentric circles. This iconography is reminiscent of the traditional division of the polity into king and estates. It assigns to Christ a position analogous to that of the king and dispenser of power. In Christ's case, this is the power to purify those on earth from moral corruption. As heavenly king he delegates this power to the lower orders, enabling them to carry out his work of purification according to their own capacities (see Sovereignty).

4 Scepticism

Erasmus' moral integrity was questioned by his opponents when he declared that, although it was not permissible to 'go against' the truth, it might be expedient in some circumstances to conceal it. He also considered careful judgment and a fine sense of timing to be of prime importance in the deployment of truth. The notion that the truth needs husbanding is best understood as an aspect of Erasmus' scepticism. He believed that human beings were unable to grasp the absolute truth by their own intellectual efforts. Through discussing arguments on both sides of a question they could arrive at an approximation of the truth, but the investigation must necessarily end in *epoche*, the suspension of judgment. Erasmus' polemic with Luther over free will illustrates this method of investigation. His *Discourse on Free Will* consists of a comparison of biblical and patristic passages for and against the concept of free will. He concludes that the human will is exceedingly weak but able, with the help of divine grace, to choose the path of salvation. Erasmus does not assert this view, however, but presents it as the more likely to be true, emphasizing that his role was not to judge matters but to discuss them. It is important to note, however, that Erasmus set limits to scepticism in the religious sphere. He believed in absolute knowledge through revelation and resorted to calculations of probability only in cases that could not be settled by the authority of Scripture and had not been determined by the doctrinal pronouncements of the Church (see Scepticism, Renaissance §3).

5 Philosophy of language

As the author of several textbooks on style and composition, Erasmus took a substantial interest in language. However, he was concerned primarily with the practicalities of teaching language skills and does not seem to have a coherent philosophy concerning the nature, origin and function of language. Pronouncements such as 'In principle, knowledge as a whole seems to be of two kinds, of things and of words. Knowledge of words comes earlier, but that of things is the more important' (the opening sentence of *De ratione studii*) are isolated statements and do not lead to a fuller discussion of the underlying issues. They suggest the metaphysical questions raised and discussed in Plato's *Cratylus*, Aristotle's *Metaphysics*, or Augustine's *On Christian Doctrine* (see Plato §15; Aristotle §11; Augustine §8), but are merely echoes of classical commonplaces. Indeed, Erasmus is concerned, not with philosophy, but with rhetoric, and more specifically, with effective methods of teaching rhetoric.

De ratione studii, a curriculum outline, continues appropriately with remarks of a pedagogical rather than a philosophical nature: 'But some people, while they hurry on to learn about things, neglect a concern for language.' Elsewhere, while discussing the relation between words and things, Erasmus claims that people who are unskilled in the use of language are 'short-sighted', 'deluded' and unable to form proper judgments about things. Once again, the philosophical implications are left unexplained. The statement therefore amounts to little more than a comment on the importance of effective communication. The subject of the dichotomy between words and things recurs in *De copia (On the Abundance of Style)* (1512). There it serves as an organizational principle (Book I deals with 'words', that is, style; Book II with 'things', that is, subject matter). As in *De ratione*, references to the dichotomy are linked with remarks on the effectiveness of communication: subject matter is obscured by the failure to organize words and expressions correctly. Indeed Erasmus seems to disavow any philosophical purpose. Considering distinctions between words and things to be a matter of theory rather than practice, he explained that the arrangement in his book had no philosophical basis, but was a 'teaching procedure'.

More significant in the context of a philosophy of language is a statement found in the prolegomena of Erasmus' edition of the New Testament. Defending his revision of the Vulgate translation, he argues that speech is made up of two things: words (which he relates to the body) and meaning (which is related to the soul). Similarly in *De copia*, a textbook on style, he writes of style being to thought what clothes are to the body. Like his remarks on the dichotomy of words and things, however, these statements operate on a rhetorical rather than a philosophical level and concern method rather than logic. He goes on, in one case, to discuss techniques of translation, in the other, to suggest techniques for varying expression. The overwhelming consensus of modern scholars is that it is futile 'to

impute a philosophy of language to Erasmus' (O'Rourke Boyle 1977) on the basis of these and other isolated remarks, or at any rate, that his thinking on the subject is ill-disciplined and 'very imperfectly worked out' (Woodward [1904] 1964). Erasmus' comments on language bear out his propensity to focus on practical application rather than on theory, a propensity also found in his religious writings with their pronounced emphasis on Christian living rather than on doctrinal definitions (see Language, Renaissance philosophy of).

6 *Philosophia Christi*

Erasmus called his *Enchiridion Militis Christiani* a 'summary guide' to Christian living. In this work he developed the concept of a *philosophia Christi*, a term which is taken from patristic writings and develops Pauline notions: the dichotomy of spirit and flesh and the inferiority of visible to invisible things. Erasmus describes the human being as having a divine soul but the body of 'a brute beast'. He therefore places emphasis on the inner man rather than on the observance of rites, on faith rather than works. He does not reject the ceremonial aspect of religion out of hand, but reduces its role to that of a crutch aiding the weak in their progression towards a more perfect faith. Erasmus also takes a stand against scholastic theologians who place inordinate trust in Aristotelian dialectics (see Major, J.). The philosophy of Christ advocated by him does not require scholarship, but manifests itself in the believer's heart and through the conduct of their life. The body of theological work published by Erasmus - editions and translations of patristic writings; an annotated edition of the New Testament; paraphrases and commentaries on Scripture - indicates the focal points of his religious thought. In Erasmus' view, the essence of the Christian faith could be discovered, not from the disputations of scholastic theologians, but from the life of Christ related by the evangelists and the interpretations of the divine word by the early Church Fathers.

Erasmus was not a systematic philosopher, but a keen observer of society, commenting on the questions that agitated his contemporaries and at the same time shaping the opinions of his own and future generations. His call for reform of church and society merited him the title of a 'forerunner' of the Reformation, and his pedagogical works had a pervasive influence on curriculum in his time. His criticism of the scholastic method and his scepticism in particular commended him to readers in the Age of Enlightenment. This induced a modest Erasmian renaissance after a decline in popularity during the seventeenth century, especially in areas where the Counter-Reformation had led to a strict enforcement of censorship laws. We find, however, that the positions taken by Erasmus on individual questions are not integrated into a whole: patriarchal government is advocated along with the egalitarian ideal of consensus and consent; scepticism is juxtaposed with devout and unquestioning belief; anthropological optimism with the reduction of the human will to a spark kindled by divine grace. Erasmus' ideas are clearly modified by the tenets of the Catholic Church. His belief in the human potential is tempered by the doctrine of God's omnipotence, his rationalism by the tenet of God's inscrutability, his intellectual curiosity is circumscribed by articles of faith, and his scholarly findings subjected to the verdict of the Church. The term 'Christian humanism' best describes Erasmus' brand of philosophy. It acknowledges that Erasmus' thought is firmly rooted in the Christian tradition and that he was a man of letters rather than a professional philosopher.

List of works

Erasmus, D. (1503-36) *Desiderii Erasmi Roterodami Opera Omnia (Complete Works of Desiderius Erasmus of Rotterdam)*, ed. J. Leclerc, Leiden: Vander Aa, 1703-6; repr. Gregg Press, 1962.(The Gregg Press edition is a facsimile reprint.)

Erasmus, D. (1503-36) *Erasmi Opuscula: A supplement to the Opera Omnia*, ed. W. Ferguson, The Hague: Martinus Nijhoff, 1933.(Collection of Erasmus' short works.)

Erasmus, D. (1503-36) *Opus epistolarum Des. Erasmi Roterodami*, ed. P.S. Allen, Oxford: Clarendon Press, 1906-47.(Collection of Erasmus' letters.)

Erasmus, D. (1503-36) *Des. Erasmi Opera Omnia (Complete Works of Desiderius Erasmus)*, Amsterdam: North Holland, 1969-.(New Critical Latin edition, in progress. It does not include Erasmus' correspondence.)

Erasmus, D. (1503-36) *The Collected Works of Erasmus*, Toronto, Ont.: University of Toronto Press, 1974-. (English edition in progress. *Ratio verae theologiae* and *De bello Turcico* are forthcoming; the other works mentioned in this article have appeared.)

Erasmus, D. (1503) *Enchiridion Militis Christiani (The Handbook of the Christian Soldier)*, in *The Collected Works of Erasmus*, vol. 66, Toronto, Ont.: University of Toronto Press, 1988.(Develops Erasmus' concept of the *philosophia Christi*.)

Erasmus, D. (1511) *In Praise of Folly*, in R.M. Adams (ed.) *The Praise of Folly and Other Writings*, New York: W.W. Norton, 1990.(Includes *Paraclesis*, *Querela Pacis*, the foreword to the New Testament, a selection of colloquies and letters, and critical essays by modern scholars.)

Erasmus, D. (1512) *De copia (On the Abundance of Style)*, in *The Collected Works of Erasmus*, vol. 24, Toronto, Ont.: University of Toronto Press, 1978.(One of Erasmus' many textbooks on style. Book 1 deals with style, Book 2 with subject matter.)

Erasmus, D. (1512) *De ratione studii (On the Method of Study)*, in *The Collected Works of Erasmus*, vol. 24, Toronto, Ont.: University of Toronto Press, 1978.(A curriculum outline and approach to a philosophy of language from pedagogical standpoint.)

Erasmus, D. (1515) 'Dulce Bellum Inexpertis' (War is Sweet to the Inexperienced), in M. Mann Phillips (trans.) *Erasmus on his Times*, Cambridge: Cambridge University Press, 1967.(Outlines Erasmus' pacifism in the light of classical notions of humanity and the idea of Christian fellowship.)

Erasmus, D. (1516) *Institutio Principis Christiani (The Education of a Christian Prince)*, in *The Collected Works of Erasmus*, vol. 27, Toronto, Ont.: University of Toronto Press, 1986.(Presents Erasmus' ideas on sovereignty and good government.)

Erasmus, D. (1517) *Querela Pacis (Complaint of Peace)*, in *The Collected Works of Erasmus*, vol. 27, Toronto, Ont.: University of Toronto Press, 1986.(Concerned with the maintenance of peace and concord, appeals to Christian virtues in an argument against the necessity of war.)

Erasmus, D. (1518) *Ratio verae theologiae (The Method of True Theology)*, in H. Holborn (ed.) *Desiderius Erasmus Roterdamus: Ausgewählte Werke*, Munich: C.H. Beck, 1933.(On the aims and methods of theological studies.)

Erasmus, D. (1524) *Erasmus-Luther: Discourse on Free Will*, trans. E. Winter, New York: Frederick Ungar, 1961.(Erasmus' investigation of the concept of free will, using biblical and patristic sources; part of a major dispute with Luther.)

Erasmus, D. (1529) *De pueris instituendis (On the Education of Children)*, in *The Collected Works of Erasmus*, vol. 26, Toronto, Ont.: University of Toronto Press, 1985.(A comprehensive statement of Erasmus' views on the goals of education and the respective roles played by parent, teacher and pupil in the process of education.)

Erasmus, D. (1530) *De bello Turcico (On War Against the Turks)*, in *Des. Erasmi Opera Omnia*, vol. 3, Amsterdam: North Holland, 1986.(Accepts the concept of a 'just war' against the Ottoman Empire but recasts it as a primarily spiritual conflict. *De bello Turcico* is partially translated into English in *The Erasmus Reader*.)

Erasmus, D. (1990) *The Erasmus Reader*, ed. E. Rummel, Toronto, Ont.: University of Toronto Press.(This collection includes a partial translation of *De bello Turcico*.)

Eriugena, Johannes Scottus (*c*.800-*c*.877)

Johannes Scottus Eriugena is the most important philosopher writing in Latin between Boethius and Anselm. A Christian Neoplatonist, he developed a unique synthesis between the Neoplatonic traditions of Pseudo-Dionysius and Augustine. Eriugena knew Greek, which was highly unusual in the West at that time, and his translations of Dionysius and other Greek authors provided access to a theological tradition hitherto unknown in the Latin West. From these sources, Eriugena produced an original cosmology with Nature as the first principle. Nature, the totality of all things that are and are not, includes both God and creation, and has four divisions: nature which creates and is not created, nature which creates and is created, nature which is created and does not create, and nature which is neither created nor creates. These divisions participate in the cosmic procession of creatures from God and in their return to God. As everything takes place within Nature, God is present in all four divisions. Eriugena influenced twelfth-century Neoplatonists but was condemned in the thirteenth century for teaching the identity of God and creation.

1 Life and writings

Little is known about Eriugena's life. His exact place and date of birth are unknown, but contemporary sources refer to him as *scottus*, meaning 'Irish', and he signed one of his manuscripts with the pleonasm 'Eriugena' (Irish born). No evidence of his education survives. Johannes joined the court of Charles the Bald, possibly in the 840s, and achieved recognition as a liberal arts master. Two partial commentaries on *De nuptiis Philologiae et Mercurii (The Marriage of Philology and Mercury)*, the liberal arts handbook of the late Latin author Martianus Capella, survive from Eriugena's period as royal master (see Encyclopedists, medieval §4).

Eriugena was commissioned to refute a treatise by a Saxon monk, Gottschalk, who interpreted Augustine as teaching a twofold predestination: of the elect and of the damned. Eriugena's reponse, *De divina praedestinatione (On Divine Predestination)*, denied predestination by defending God's transcendence and goodness. God, being perfectly good, wants all humans to be saved. Humans, however, damn themselves through their own free choices. God, who is outside time, cannot be said to '*fore*-know' or to '*pre*-destine', terms which involve temporal predicates. Hence God does not predestine souls to damnation (see Eternity). Due to a perceived overemphasis on human free-will in the salvific process, Eriugena was accused of Pelagianism (the heresy that human beings can be saved through their own resources rather than by divine grace) (see Pelagianism), and *De divina praedestinatione* was condemned in France at the councils of Valence (855) and Langres (859). While purporting merely to interpret Augustinian texts, this early treatise is philosophically significant for its rationalistic, dialectical analysis of key theological concepts.

Despite the condemnations of *De divina praedestinatione*, Eriugena continued to have the patronage of Charles the Bald, who invited him to translate the writings of Dionysius the Areopagite, a mysterious Christian Neoplatonist, possibly of the sixth century, who imitated Proclus and purported to be Dionysius, the first convert of St Paul at Athens (see Pseudo-Dionysius). This author had been wrongly identified with St Denis, patron saint of France. For Dionysius, it is more true to say 'God is not' than 'God is', since God is 'above all the things that are and are not'. Eriugena adopted Dionysius' affirmative and negative theology, according to which denials concerning God are 'more true', 'better', 'more apt', than affirmations.

Eriugena's major dialogue, *Periphyseon* or *De divisione naturae (On the Division of Nature)* was completed around 867. He also wrote a commentary on Dionysius' *Celestial Hierarchy (Expositiones in hierarchiam coelestem)* and on Maximus' *Ambigua*. A fragmentary commentary on the Gospel of St. John and a sermon, *Homilia in Johannem (Homily on the Prologue to St John's Gospel)*, were also written probably in the late 860s or 870s. A number of poems also survive. It is probable that Eriugena died sometime around 877; an apocryphal tale, dating from the twelfth century, records that he was stabbed to death by his students.

2 Sources

Eriugena had no direct knowledge of Plotinus, Porphyry or Proclus. He appears to have known Plato's *Timaeus* in Calcidius' translation (see Plato). He knew the Pseudo-Augustinian paraphrase of Aristotle's *Categories*, Rufinus's Latin translation of Origen's *De principiis (On First Principles)*, and Boethius' trinitarian tracts and *De*

consolatione philosophiae (Consolation of Philosophy) (see Boethius, A.M.S.; Origen). His chief authorities were Augustine, Ambrose, Hilary of Poitiers and Jerome, among the Latin Fathers, but he more often expresses a preference for Eastern Church Fathers, in particular Dionysius and the Cappadocians, Basil, Gregory of Nazianzus and Gregory of Nyssa, whose *De hominis opificio (The Creation of Man)* he translated under the title of *De imagine (On the Image of Good)*. He also translated Maximus Confessor's *Ambigua (Difficult Questions of Interpretation [in Pseudo-Dionysius])* and *Quaestiones ad Thalassium (Questions to Thalassius)* and he may have translated Epiphanius's *Anchoratus (De fide) (The Hermit State (On Faith))* (see Patristic philosophy).

Given the available resources, Eriugena was exceptionally learned, but his genius lay in being able to bring all these 'authorities' together in a new cosmological framework. Eriugena enthusiastically incorporated many Greek Christian theological concepts: God, the One, creates by self-emanation; creation is a timeless event and hence ongoing and always contemporary; human nature is originally a Platonic Idea in the mind of God. Humans fail to understand their true nature as image of God in God because they are distracted by created, temporal images (*phantasiai*), leading to a fall into the spatio-temporal realm of sense. However, through intellectual contemplation (*theoria*) and divine illumination (which is the divine self-manifestation, *theophania*), humans may achieve unification (*henosis*) with God, deification (*theosis*). God became man so that humans can become God (see Platonism, early and middle).

3 The divisions of nature

The *Periphyseon*, or *De divisione naturae (On the Division of Nature)*, a long dialogue in five books between an anonymous teacher and his student, is Eriugena's major philosophical treatise. It opens with an all-encompassing definition of its subject matter. Nature is the general term 'for all things that are and all things that are not' (CXXII I.441a), including both God and creation. The first principle of nature is God, 'the cause of all things that are and that are not' (I.442b). Nature is divided into four 'species', echoing similar divisions in Augustine and Marius Victorinus: first, that which creates and is not created (that is, God); second, that which creates and is created (that is, Primary Causes or Ideas); third, that which is created and does not create (that is, Temporal Effects, created things); and fourth, that which is neither created nor creates (that is, non-being or nothingness).

Eriugena proceeds to list five ways (*quinque modi*) in which things may be said to be and not to be. According to the first mode, things accessible to the senses and the intellect are said to be, whereas those which - through their excellence - transcend our faculties are said not to be. According to this classification, God is said not to be; he is 'nothingness through excellence' (*nihil per excellentiam*). The second mode of being and non-being is based on the 'orders and differences of created natures', whereby if one level of nature is said to be, those orders above or below it are said not to be. According to this mode, to affirm 'man' is to negate 'angel' and vice versa. This mode invokes the medieval hierarchy of being and at the same time subverts it by relativising the notion of being: only one level of the hierarchy can at any time be said to be. The third mode asserts that *actual* things are, whereas *potential* things still caught up 'in the secret recesses of nature' are not. The fourth mode says that things which the intellect contemplates truly are, whereas material things caught up in generation do not truly exist. The fifth mode says that humans sanctified by grace are, whereas sinful humans are not.

Eriugena's discussion of being and non-being is subject to a dialectic of affirmation and negation. Being and non-being, then, are correlative categories; something may be said to be under one mode and not to be under another mode. These modes further must be taken into account when assessing Eriugena's metaphysical statements. Thus when Eriugena calls God 'nothing,' he means that God transcends all created being. Matter is called 'nothing through privation' (*nihil per privationem*), and created things are called 'nothing' because they do not contain in themselves their principles of subsistence (see Being).

Periphyseon Book I examines the first division, God. The Aristotelian categories do not properly apply to God, who is not literally (*proprie*) substance or essence, does not possess quantity or quality, has no relations and is not in place and time. God transcends all. His 'being' is beyond being. God is a 'nothingness' whose real essence is unknown to all created beings, including the angels. Indeed, God's nature is unknown even to himself, since he is the 'infinity of infinities' and hence beyond all comprehension and circumscription. God does not know evil, and, in a real sense, God may be said not to know anything (see God, concepts of).

However, for Eriugena, God also creates himself. He manifests himself in theophanies. This self-creation is God's

self-manifestation and also the expression of the Word and the creation of all other things, since all things are contained in the Word. The Word enfolds in itself the Ideas or Primary Causes of all things. God is 'all in all'. All things are in God: '… the Creative nature permits nothing outside itself because outside it nothing can be, yet everything which it has created and creates it contains within itself, but in such a way that it itself is other, because it is superessential, than what it creates within itself' (III.675c). God's transcendent otherness above creatures is precisely that which allows creatures to be within God and yet other than God. Eriugena stresses both the divine transcendence and immanence in creation, which is at the same time the immanence of creatures within God (see Creation and conservation, religious doctrine of).

God and the creature are one and the same: 'It follows that we ought not to understand God and the creature as two things distinct from one another, but as one and the same. For both the creature, by subsisting, is in God; and God, by manifesting himself, in a marvellous and ineffable manner creates himself in the creature' (III.678c). Eriugena's assertion that God is the 'form of all things' (*forma omnium*) led to the accusation of heresy, an accusation which fixates on one side only of Eriugena's dialectical reasoning. Although Eriugena asserts the identity of God and creation, he explicitly rejects the view that God is the 'genus' or 'whole' of which the creatures are 'species' or 'parts'. Only metaphorically (*metaforice*, *translative*) can it be said that God is a 'genus' or a 'whole'. The immanence of God in creation is balanced by God's transcendence above all things. God is both form of all things and without form.

Periphyseon Book II discusses the Primary Causes located in the mind of God. This doctrine combines the Platonic theory of Forms, Dionysius's discussion of the divine names and the Stoic-Augustinian notion of eternal reasons. The number of causes is infinite and none has priority over the other; for example, Being is not prior to Goodness, or vice versa. Each is a divine theophany. The very nature of these Causes is to flow out from themselves, bringing about their Effects. This outflowing (*exitus*) creates the whole universe from the highest genus to the lowest species. In this causal procession, like produces like; incorporeal causes produce incorporeal effects (see Causation). All created things are essentially incorporeal, immaterial, intellectual and eternal. Place and time are definitions which locate things, and since definitions are in the mind, then place and time are also in the mind. The sensible, corporeal spatio-temporal appearance of things is produced by the qualities or 'circumstances' of place, time, position and so on, which surround the incorporeal essence. The whole spatio-temporal world and our corporeal bodies are a consequence of the Fall, an emanation of the mind.

Book III discusses the nature of creation from nothing (*ex nihilo*). 'Nothing' has two meanings. The lowest rung in the hierarchy of being, unformed matter, is 'almost nothing' (*prope nihil*), 'nothingness through privation' (*nihil per privationem*). In contrast, God is non-being through excellence. Creation from nothing cannot mean creation from a principle outside God, since there is nothing outside God. *Ex nihilo* creation then means 'out of God's superabundant nothingness'. God creates out of himself and all creation remains within him.

Books IV and V discuss the return (*reditus*) of all things to God. Corporeal things will return to their incorporeal causes, the temporal to the eternal. The human mind will achieve reunification with the divine, and then the corporeal, temporal and material world will become essentially incorporeal, timeless and intellectual. Human nature will return to its Idea in the mind of God. This perfect human nature is paradise. There is a general return of all things to God. Humans who refuse to let go of the 'circumstances' remain trapped in their own phantasies, and this constitutes hell. The elect achieve a special deification whereby they will merge with God completely, as lights blend into the one light. Neither hell or heaven are localized; for Eriugena, they are intellectual states.

Eriugena's anthropology has been the focus of much philosophical interest in the twentieth century. For Eriugena, 'rational animal' does not adequately define human nature, nor is humanity a microcosm: humanity is an Idea eternally made in the mind of God. Perfect human nature is omniscient and omnipotent. Human nature is open to infinite possibility and perfectibility (see Perfectionism).

4 Influence and significance

Eriugena had immediate influence in France, notably at the schools of Laon, Auxerre and Corbie. His translations of Dionysius were widely used into the thirteenth century. His *Vox spiritualis (The Spiritual Voice)* or *Homilia in Johannem* (often attributed to Origen) was widely read in the Middle Ages. The *Periphyseon* was popular in the twelfth century especially in the paraphrase of Honorius Augustodunensis; Hugh of St Victor, Alanus of Lille,

Suger of St Denis and William of Malmesbury were all influenced by Eriugena. In the thirteenth century, the *Periphyseon* was associated with the writings of David of Dinant and Amaury of Bène, two theologians at the University of Paris, and was condemned with them in 1210 and 1225. According to Thomas Aquinas, Amaury of Bène was condemned for saying that God is the formal principle of all things, an accusation of pantheism, which recalled Eriugena's statement that God is the 'form of all things' (*forma omnium*). In the later Middle Ages both Meister Eckhart of Hochheim and Nicholas of Cusa were sympathetic to Eriugena and familiar with his *Periphyseon*. Interest in Eriugena was revived by Thomas Gale's edition of *De divisione naturae* (1681). Hegel and his followers saw Eriugena as the father of German idealism (see German Idealism). Critical editions of his major works are only now being produced.

Eriugena is an original philosopher who articulates the relation between God and creation in a manner which preserves both divine transcendence and omnipresence. His theory of human nature is rationalist and intellectualist. His theory of place and time as defining structures of the mind anticipates Kant, and his dialectical reasoning prefigures Hegel. Eriugena is a mystic who emphasises the unity of human nature with God.

Erotic art

Erotic art is art with a sexual content, which may be more or less overt. The presence of sexual content, however, is not sufficient for a work of art to be considered erotic. Although there is more than one sense in which a work can be said to be erotic, an erotic work of art must aim at and to some extent succeed in evoking sexual thoughts, feeling or desires in the spectator, in virtue of the nature of the sexual scene it represents and the manner in which it represents it. This aim, definitive of erotic art, may be a work's principal aim, but need not be. Erotic art often tends to express the artist's interest in and attitude towards sexuality; and whether or not it does, seeing it as expressing the artist's sexuality is likely to contribute towards the spectator's sexual arousal. An erotic work of art has an intended audience of a more or less specific kind, most frequently men. Erotic art is distinguished from pornography in at least two ways. First, pornography lacks any artistic intent. Second, its main aim is not only to stimulate the spectator sexually but to degrade, dominate and depersonalize its subject, usually women. This article is restricted in scope in at least two ways. First, it concerns exclusively the visual arts. Second, its focus is Western art, and primarily art from the Renaissance onwards.

1 Main questions

The chief philosophical questions in the aesthetics of erotic art are: (1) What is the distinction, within art, between erotic and non-erotic art, and how sharp are the boundaries of this category? (2) What are the ideological implications, if any, of the different forms and manners of erotic art, and what, in particular, is the distinction between erotic art and pornography? (3) How can erotic art in fact be art, or something properly eliciting an aesthetic response that is traditionally characterized as disinterested, when it is also aimed at provoking sexual desire, the very paradigm of an interested reaction? (4) In what ways might the criteria for assessing erotic art differ from those appropriate to other sorts of art, and how does the degree of eroticism of erotic art connect, if at all, to its value or worth as art? This entry will be devoted almost exclusively to (1) and (2).

2 The concept of erotic art

A good proportion of the work of many great visual artists - Rubens, Ingres, Delacroix, Degas, Rodin, Gauguin, Matisse, Magritte, Munch, Klimt, Picasso, Modigliani - is unquestionably erotic. But what is it, precisely, for art to be erotic? It seems that, at a minimum, it must have sexual content. Though sexual content may be either overt or covert, let us first consider art with overt sexual content. Typically, this takes the form of depictions of unclothed or semi-clothed human beings, alone or accompanied, at rest or performing actions of a sexual nature. Yet for art to be accounted erotic, it must do more than represent the naked human body or otherwise make reference to sexual matters: not all art concerned in some way with sexuality is automatically erotic. Anatomical sketches of genitalia, a realistic study of a gynaecologist's examining room, or a modern comic strip featuring pneumatic bimbos, are not erotic, despite the sexual content they include. Rather, erotic art is art that treats its sexual content in a particular way or projects a certain attitude towards it. Erotic art is art aimed at arousing sexual interest, at evoking sexual thoughts, feelings or desires in viewers, in virtue of what it depicts and how it is depicted, and which achieves some measure of success in doing so. The intent to awaken and reward sexual interest through what is depicted can be taken as criterial of at least central cases of erotic art. The erotic work of art does more than refer to or acknowledge human sexuality; rather, it expresses an involved attitude towards it, whether of fascination, obsession or delectation, and in addition invites the viewer to engage their imagination along similar lines.

Erotic art typically aims not only to activate the viewer's sexuality but to reflect that of the artist. That is to say, erotic works usually embody a perspective on what is depicted that suggests sexual interest on the maker's part. Furthermore, the sense of sharing in what at least appears to have been sexually stimulating to the artist often plays a causal role in the viewer's own stimulation. It is worth emphasizing that the sexual response occasioned by erotic art occurs largely on the plane of imagination, consisting primarily of thoughts, images and feelings, and rarely goes as far as full physiological arousal; the upshot of engagement with erotic art is imagined desire as often as it is real desire.

As suggested above, the term 'erotic art', in its primary usage, covers art that is aimed at stimulating sexual thoughts and feelings in its target audience, and which at least minimally succeeds. But this gives way to two

secondary usages, according to which fulfilling either the intentional condition or the success condition (somewhat modified) independently qualifies a work as erotic. On the first such usage, a work counts as erotic if it is ostensibly aimed at stimulating sexual thoughts and feelings, even when it does not succeed in doing so; on the second, a work counts as erotic if it succeeds noticeably in stimulating viewers sexually, even when it is not intended or even apparently intended to do so. In addition, for works of art that are erotic in the central sense, it is natural to employ 'erotic' as a comparative term as well as a classificatory one. There are works one describes as mildly erotic and those one describes as highly erotic, depending on the degree of sexual involvement they tend to sustain.

Finally, perhaps some works of art reasonably accounted erotic neither aim at nor achieve viewer arousal (in other words, sexual thoughts, feelings or sensations directed towards what is depicted), but are instead erotic merely in virtue of the fact that they facilitate the imagining of erotic states of others, without erotic involvement as such on the viewer's part - without the viewer identifying with or entering into those states, either in reality or in imagination.

3 Instrumentally erotic art and anti-erotic art

With some erotic art, the evocation of erotic feelings is a secondary aim, employed or manipulated by the artist in order to achieve some further end, such as wry humour (for example, Tom Wesslemann's caricatures of pulchritude, in his 'Great American Nudes' series, or Mel Ramos's exaggeratedly voluptuous pin-ups), social commentary (Degas's monotypes of brothel scenes), or psychological disorientation (Magritte's or Dali's recombinant sexual imagery). We might label such art 'instrumentally' erotic art. As a result of these secondary aims, the excitatory tendency of such works may be weakened or even wholly neutralized. In some limiting cases works are in effect *about* erotic art - they comment on or satirically appropriate the conventions and mechanisms of normal erotic art - but without being erotic in the primary sense, that is, without being ultimately aimed at sexually engaging the viewer. Such art may be accounted erotic in virtue of the fact that it leads the viewer to question the presuppositions and consequences, social and otherwise, of erotic responses, without inviting or even permitting viewers to have such responses.

Some other cases of works representing sexual matters without appearing clearly erotic serve to illuminate further the boundaries of the category:

(1) Lysippus' *Aphrodite*, Botticelli's *Birth of Venus*, or Cranach's images of Eve occasion some hesitation if classified as erotic. Probably this is because we take the primary intent of the artist to have been to embody ideals of the human form, male and female, and not to prompt imaginative erotic engagement on the part of viewers of either sex. But this may be ingenuous; at any rate, such a line could not plausibly be extended to exclude from the erotic Donatello's sensuous, almost coquettish *David*.
(2) Picasso's *Demoiselles d'Avignon* occasions hesitation of a different sort. Though the painting presents women who are not only nude but in fact prostitutes, they are depicted in a highly nonrealistic mode, which shortcircuits erotic involvement, as well as drawing attention primarily to the painting's formal and expressive dimension.
(3) Judy Chicago's *The Dinner Party*, an elaborate sculptural installation, uses female genital imagery in a celebratory though arguably not erotic way; its sexual content is of a sort that is purely symbolic, rather than sexually involving.
(4) Though displaying some of the hallmarks of erotic art, Lucian Freud's paintings of naked subjects are not obviously erotic, being more evocative of the *boucherie* than the *boudoir* - an observation even truer of the images of nudes in Francis Bacon's paintings. Philip Pearlstein's superrealist figure paintings or, in another vein, Dubuffet's quasi-paleolithic images of squashed and splayed humanity belong here as well.

These latter artists - Bacon, Freud, Pearlstein, Dubuffet - are not aptly described merely as non-erotic - as is, say, a Corot landscape or Chardin still life - but rather as anti-erotic. Thus in a broader sense they, unlike Chardin or Corot, are erotic after all, that is to say, concerned with sexuality in a way that reflects the sexual interests of the maker and engages those of the viewer, if not in a positive manner. De Kooning's raw and primitivist images of women also come naturally to mind in this connection as well, though the case can be made that those images project a more ambivalent attitude to human sexuality than those of, say, Bacon - an admixture of terror, awe and admiration.

4 Covertly erotic art

It is relatively easy to give plausible examples of erotic works of art that contain no explicit depictions of sexuality or nakedness: Georgia O'Keeffe's landscapes and still lifes, with their oblique evocation of female anatomy; Caravaggio's paintings of Bacchus or St John the Baptist, with their coded references to homosexual experience; or Bernini's marble of St Teresa in spiritual ecstasy, a state readily transposed by the viewer into its profane cousin. The criterion of covert sexual content, however, remains unclear. Depiction of objects recognized as sexually symbolic - umbrellas or fruit, for example - especially when juxtaposed with human subjects, may be a typical indication of such content, but can hardly serve as a general mark. According to some writers, virtually all art has covert sexual content in virtue of being the expression of unconscious wishes or fantasies of a sexual sort. Thus, for Wollheim (1987), Ingres' history paintings, Bellotto's landscapes with buildings, and Poussin's landscapes with water are as substantially imbued with sexuality as Goya's *Naked Maja* or Titian's *Venus of Urbino*.

Even so, it seems that not all covertly sexual art is usefully considered erotic, but only that which is plausibly aimed, if unconsciously, at exciting sexual thoughts or feelings in target viewers, and which succeeds in doing so. In putative cases of covert sexual content, the arousal of the viewer of intended orientation and appropriate background may be just what signals the presence of such content and justifies its ascription.

5 The relationality of erotic art

If a painting is erotic, this is in virtue of its being aimed at and to some extent its eliciting an erotic response *from a certain class of viewer* - the work's intended or target audience. Such classes may be delimited not only by the requirements of sensitivity and background knowledge but also by less acquirable ones of physiological make-up or sexual orientation. Thus, a painting may be erotic in virtue of its being designed to produce an erotic reaction in heterosexual males, elderly homosexual males, young heterosexual girls, homosexual women, or bisexuals of either sex. There is a fact of the matter, albeit a hazy one, about whether a given painting is erotic, but it is an inherently relational one, whose nature is only fully evident when the group targeted for response is identified. Indeed, according to Nochlin (1988), '…. the very term "erotic art" is understood to imply the specification "erotic-for-men".' Still, once such implicit indexing has been made explicit, it may then be cancelled, so as to recognize art that is erotic relative to other target groups.

6 Social and political aspects of erotic art

Recent writers on erotic art stress the way in which entrenched genres and conventions of representation embody dominant ideas and assumptions about the nature of men and women and their proper relationship. Paintings such as Delacroix's *Death of Sardanapalus*, Gerome's *Oriental Slave Market*, Ingres' *The Turkish Bath* or *Jupiter and Thetis* lend themselves readily to such analysis. For example, Nochlin (1988) speaks of 'the power relations obtaining between men and women inscribed in visual representation' as a focus of her investigations.

Equally frequently noted is the element of voyeurism in erotic art. It is said that the spectator is a voyeur (at least fictionally), and that the work of art often reinforces or echoes this by depicting a spectator who, together with the viewer, regards the erotic object. Furthermore, the implicit or explicit voyeurism of erotic art is sometimes held to reflect the necessary impotence of the artist in respect of the imaginary and thus unattainable individuals depicted within their art.

Finally, the relationship of erotic art and pornography has been much debated. They may be distinguished, arguably, in at least two ways. First, pornography has, perhaps by definition, no significant artistic aspect. That is to say, pornography makes no credible appeal to viewers to consider the mode and means of depiction, as opposed merely to what is depicted; pornography, unlike art of any kind, is wholly transparent in both aim and effect. Second, pornography has, as a central intent and characteristic result, not only the stimulation of sexual feelings or fantasies in viewers, but the degradation, domination and depersonalization of what it depicts, usually women. Courbet's *Sleep*, which shows two beautiful nude women in the arms of Morpheus and each other, or Schiele's 1917 *Reclining Woman*, which presents its subject provocatively spread-legged and scarlet-nippled, perhaps court dismissal as pornography by some of these criteria, but on reflection they remain at a safe distance from it. Though the images in question are starkly arousing, even exploitative, the technique of their construction, the style in which they are rendered, the preceding art history they encapsulate, and the entrée they afford into

their makers' psyches, are at least as absorbing as what they flatly represent, and conspire to redeem them as art.

Error and illusion, Indian conceptions of

From the earliest Indian speculation, illusion has been key in the exposition of Indian mysticism. In classical philosophy proper, all schools take positions concerning illusion (sometimes called error) early in their histories, and in some schools successive refinements are achieved over the centuries.

There is a wealth of reflection on illusion from different angles - for example, psychological treatments that differentiate seven, eight or ten types of illusion, identifying causal factors for each variety. Illusion is taken to have ontological and epistemological ramifications brought out in elaborations of one or another metaphysical system.

The sections of classical philosophical texts devoted specifically to illusion generally presuppose or smuggle in criteria of veridical awareness in the midst of causal analyses or systematic explanations of such stock examples as a snake appearing as a rope, a piece of shell appearing as silver, two moons, a 'red' crystal with a red flower behind it, a mirage, the 'blue' of the sky, and dreams. Arguments in support of a criterion, or set of criteria, of veridicality do appear, however. How we understand (1) what counts as a veridical and a nonveridical experience and (2) why individual cases of illusion occur are distinct issues, but positions taken on the former determine important parts of conceptions about why illusions occur. A peculiar stylistic feature of the later and more refined philosophic treatments is a polemical ordering, where a first view's inadequacy is shown to lead to a second view whose inadequacy, demonstrated in turn, leads on to a better theory, and so on, until we reach the right view, which is thus established by a sequence of arguments.

1 Illusion in Indian metaphysical systems

In proclaiming the supreme value of a mystical experience, both Upaniṣadic (*c.*800 BC and on) and Buddhist texts (*c.*300 BC and on) put illusion to use as an analogy. This is most dramatically exemplified in the epithet *buddha*, which in Sanskrit is the past passive participle of the common verb for 'to awaken': thus 'the Awakened', implying that those who do not have the *nirvāṇa* experience need to awaken from their all too unpleasant dreams to a blissful reality (see Nirvāṇa). Similarly, in the Advaita Vedānta philosophy, which is one of two or three major classical systematizations of the thought of the early Upaniṣads, an illusion analogy is central to a teaching of an experience of Brahman, the Absolute and One, as supremely valuable (see Brahman).

It is worth dwelling on illusion within the Advaita system. The use of illusion as a metaphor for mysticism is generalized to a metaphysical position: as the illusory snake is to the real rope, so the manifest universe, in its diversity, is to Brahman, the supreme reality, who is One and Nondual. Later Advaitins bring out the tension between diverse appearances and Brahman's unity. The great eighth-century philosopher Śaōkara (§2) is more concerned with defending an understanding of mystical awareness of Brahman: like the experience of a rope sublating a snake appearance, Brahman-awareness sublates all other modes of experience.

Śaōkara uses the term *adhyāsa*, commonly translated 'superimposition', to indicate the relation of the world to Brahman. But that is from our point of view. Strictly speaking, there is no relation of Brahman *to* the world (no two-way street), since (as maintained by the early interpreter Padmapāda), the snake simply does not exist. On our side, the world, like the snake, does of course appear. Consonantly, Advaitins say (again from 'our side', from the perspective of spiritual ignorance) that the world has a problematic ontic status 'impossible to explain' (*anirvacanīya*). Matching such a conception is the view (see §3) that the content of an illusory awareness cannot be explained (*anirvacanīya*) as real or not real. In applying to the world the category 'being impossible to explain' (*anirvacanīyatva*), Advaitins generate an entire metaphysics. The world is not not-real because it appears (unlike the horn of a rabbit), but it should not be said to be real because it is (or is to be) sublated.

Illusion likewise plays a central role in Buddhist philosophy, both with the Mādhyamika of Nāgārjuna (*c.*150-200 CE) and his followers, and the Yogācāra of Vasubandhu (*c.*400), Dignāga (b. *circa* 480), Dharmakīrti (*c.*600-60) and company (see Buddhism, Mādhyamika: India and Tibet; Buddhism, Yogācāra school of). Nāgārjuna says that his seeming to maintain positive philosophical positions in spite of his proclamation that everything is empty is to be understood as analogous to the unreal words of an imaginary, magical man. 'Everything is empty' is no exception to itself, since that statement too is empty, like statements in an illusion.

Nāgārjuna's appeal to this possibility seems integral to his entire outlook, but just what that outlook is (must a sceptic have an outlook?) is controversial among modern interpreters, as indeed it was in classical debates. A more straightforwardly theoretical approach to illusion is made by Vasubandhu and his school. Though we may suspect peculiarly Buddhist motivations having to do with defending the possibility of *nirvāṇa* experience, the great Yogācārin launches a project known in the West from Cartesian epistemology - or from what is called the argument from illusion for phenomenalism, and a perceptual core common to illusion and veridical experience (see Perception, epistemic issues in §5). Vasubandhu embraces a phenomenalism of atomic awareness-events, events of colour, sound, feeling, and so on, arguing that these are what we directly experience, as is proved by illusion. There must be a phenomenal core common to both veridical and illusory awareness since illusions do occur that are indistinguishable from veridical experiences, at least at the time of their occurrence.

In subsequent philosophic discussion both within Buddhist traditions and outside, the term 'error' (Sanskrit, *bhrama*, *bhrānti*) is used to refer to perceptual illusion in a neutral, non-question-begging fashion. Usually the term is not used to refer to other types of cognitive failure, such as false claims or faulty logic. However, on some views - notably taken by some Yogācārins as well as proponents of an influential Mīmāṃsaka stance (to be explained) - the error in what is ordinarily taken to be perceptual illusion is attributed to nonexperiential factors. There is no nonveridical experience according to these views. Thus the explananda targeted by these theories are patterns of everyday speech and behaviour where we commonly take cases of (experiential) error, or illusion, to occur.

Later Yogācārins view illusion pragmatically, but Dignāga, an important theorist standing about midway in the history of the school, sees error as a matter of incorrect interpretation, with no illusion on the level of experience itself. Although he claims that his epistemological positions are independent of such considerations as whether things known are viewed as 'external' or (as Buddhists are wont to say) 'Void', it seems plausible that the metaphysics of atomic awareness-events contributed to his interpretationalist stance - for how with a phenomenal core seen as reality could there be illusion in experience?

Philosophers belonging to Indian realist schools are called upon to defend their views against objections based on the occurrence of illusions. The great names from the Mīmāṃsā and the Nyāya-Vaiśeṣika traditions forge positions on illusion in consonance with a realism about the objects revealed by veridical experiences - and, surprisingly, the objects of nonveridical experiences.

2 Criteria of veridicality

The question of the nature of veridicality - what veridicality is - connects with the question of how it is known, that is, how an awareness is known to be veridical. A centrepiece of Nyāya-Vaiśeṣika realism (henceforth, for convenience, simply 'Nyāya') is what may be called a correspondence view: facts are what they are independently of consciousness (about which there are other facts), and what it is for an awareness to be veridical is for it to reveal an object, or, more precisely, an objective complex. The simplest veridical awareness makes known an objective complex: '*a* is *F*' just in case *F* (a qualifier) qualifies *a* (the qualificandum) - or, to suggest more explicitly the tie to Nyāya's ontology, just in case *a* has *F*-hood. In other words, an awareness' propositional content (*Fa*) must reflect what is in fact (*a*'s being *F*) if the awareness is veridical, according to Nyāya. An awareness with the content *Fa* is erroneous just in case *a* is not qualified by *F*. The world contains both *a* and *F* even, as will be explained, in cases of error. Finally, to be accurate, the fourteenth century philosopher Gaṅgeśa (§2), a leader of the New Nyāya school, and others as well, criticize characterizations of veridicality as simply correspondence with fact (*yāthārthya*), demanding more precise formulations. But a correspondence view may be said to be the spirit of Nyāya throughout its two-millennia history (see Nyāya-Vaiśeṣika §6).

The question of the marks whereby such a match is itself discernible is not an easy one for the realist, the Naiyāyika or any other. Before reviewing Nyāya's proposals, let us look at two other views about what veridicality is, in Mīmāṃsā - specifically, the Prābhākara branch - and in Yogācāra.

Contrasting with the Nyāya position is Mīmāṃsā, a realist school that assumes an unexpected stance (see Mīmāṃsā §2). Veridicality is identified with awareness itself: all awarenesses are veridical. The Buddhist argument from illusion to find a phenomenal core is met head on by the (Prābhākara) Mīmāṃsaka: the nature of all awareness is to reveal objects in a person's immediate environment. The question of how an awareness is known

to be veridical is understood as asking how an awareness, our own awareness, is known to have occurred. (The Prābhākara answer is, like that of the Yogācāra Buddhist, that every awareness is self-aware, while also - a departure from the Buddhist position - making the self known: thus something about the world, the awareness itself and the cognizer are all made known by a single awareness.) Why take it as given, the Prābhākara asks, that any awareness misrepresents the world? It is natural for awareness to present things as they are, and so another source of error should be assumed. Common speech and other behaviour do of course show that error occurs; this is admitted by all disputants. But no criteria for differentiating the veridical and the nonveridical are needed. Nor need we say what veridicality is, apart from specifying what awareness is and how it is different from other realities.

Coherence, or agreement with other awarenesses, is both the nature of veridicality and the criterion whereby it is discerned, according to the later Yogācāra of Dharmakīrti and others. To be sure, Dharmakīrti proposes that there are pragmatic criteria - whether action based on an (interpreted or proposition-laden) awareness leads to successful results - but since the results are themselves (proposition-laden) awarenesses, on his view, coherence seems to remain the criterion, as it clearly is with earlier members of his school.

Finally, as early as Vātsyāyana (*c*.350), whose commentary on the *Nyāyasūtra* is the oldest extant - indeed in the very opening passage of Vātsyāyana's commentary and throughout the history of the school - a pragmatic criterion is proffered as the test of veridicality. Veridical awarenesses are proved so by their fruits; nonveridical awarenesses lead to error in action, preventing us from getting what we want and avoiding things to which we are averse.

Again, what it is for an awareness to be veridical is for it to reveal a fact; but we do not know from the occurrence of an awareness *A* itself that *A* is veridical (except in the case of an apperception, where what is known is a preceding awareness). We infer *A*'s veridicality or nonveridicality - if circumstances call it into question - from whether it has proved workable in helping us get what we want and avoid our aversions.

The Nyāya pragmatism does not amount to a hidden coherentism, although to judge from the accounts given of particular types of illusion, coherence considerations are, as one might expect, appealed to. Veridical awarenesses are the results of reliable sources, and are themselves the foundations of warranted statements. If there is reasonable doubt about a statement's truth, then one turns to reliable sources of knowledge, such as perception, to resolve the doubt. According to Nyāya, it may be impossible to tell at the time of occurrence whether an ordinarily presumed veridical perception is in fact veridical, and if there is reasonable doubt about this it is here that the pragmatic criterion comes into play. Thus the epistemological default is a fallibilistic presumption of veridicality, and we are presumed not ordinarily to be called to wonder about error in our awarenesses.

3 A polemical survey of conceptions

An illuminating attempt to refute non-Naiyāyika views of error is made by the modern Nyāya philosopher Ramanuja Tatacharya in his *Pratyakṣatattvacintāmaṇi Vimarśa (Consideration of the Tattvacintāmani's [Treatment of] Perception*; 1992), which is based on the thought of Gaógeśa. The polemical ordering of his argument - whereby successive refinements or corrections of a view are shown to be inadequate until the correct one is arrived at - is typical of later classical philosophy.

Tatacharya starts by characterizing the Yogācāra view as *ātma-khyāti* ('illusion is "self-" or "internal" manifestation': *khyāti* means 'perception' or 'manifestation' and is used in a neutral way with respect to all theories considered; *ātma* means 'self', and since there is no self on the Buddhist view the term should be taken as 'internal'). With the error 'This is silver', when the object in front is instead a piece of shell, the Yogācārin holds, says Tatacharya, that the silver form that appears is an internal manifestation and that the correcting cognition 'This is a piece of shell' negates only the 'thisness' of the error. The silver form is uncorrected by the succeeding moment of consciousness (it has simply passed away, though also helping to give rise to the consciousness of a piece of shell, according to Yogācāra psychology). Illusion shows that the silver form has to be internal; 'thisness' with respect to silver cannot be external. Therefore, illusion is an internal manifestation (due, like all occurrences of consciousness, to dispositions, some common to other persons, some not).

However, if this view were correct, Tatacharya continues, the error would be appropriately verbalized as 'I am silver', not 'This is silver'. Moreover, since it is held that the silver form is no illusion, we should be able to use it

in the market. Clearly, the silver, which is the object of the illusion, does not exist, as the correcting cognition, ‘Not (this-is-silver)’, shows. The right view would then be *asat-khyāti*, ‘manifestation of the nonexistent’, a view attributable to the Mādhyamika school of Nāgārjuna. How the nonexistent can be the object of a cognition should not be asked, for cognitive objecthood is not to be understood causally, but in its own way; the existent and nonexistent are both within its range. Error is a cognition with a nonexistent object.

However, with reference to the error ‘This is silver’, the Nyāya philosopher asks whether what is nonexistent is just the silver or also the ‘this’. It cannot be the latter, for the deluded person desiring silver reaches out to pick up the piece of shell (the ‘this’), and no such action would be taken with respect to something nonexistent. And with regard to the silver, is it nonexistent everywhere or is it simply not at this locus or place? It cannot be the former, for the universally nonexistent does not appear (whereas silver is appearing in the illusion). The right view is that cognition reflects reality (*yāthārthya*); only the existent appears (*sat-khyāti*). Error is not a single cognition, but two cognitions, a perceiving and a remembering, with their distinctness unrecognized; this is *akhyāti*, ‘nonmanifestation (of the distinctness between a perception and a memory)’, a view attributable to the Prābhākara Mīmāṃsaka. What gets verbalized as ‘this’ is reflected by a (veridical) perception of an object in the perceiver’s immediate environment; what gets verbalized as ‘silver’ is reflected by a (veridical) memory acquired from previous experience of silver. Due to a causal irregularity - various causal factors influence cognition - the class character of the piece of shell (namely, ‘piece-of-shell-hood’) is not apprehended, but its similarity to silverhood, along with the causal irregularity, triggers a silverhood memory. (Memories are stored associatively.) The two cognitions get fused, with no awareness of their distinctness. The deluded person thus reaches out to pick up what is presented experientially. The correcting cognition works with respect to the failure to grasp the distinctness. When that failure ceases, the activity based on it ceases. Error is just a matter of activity (including speech-behaviour) that can come to be corrected, not of a cognition’s object or content. Neither perceiving nor remembering manifests anything except the real. All cognition reflects reality. Thus is the right view established.

However, from the Nyāya perspective, it is a person looking to gain silver who moves to pick up the ‘this’ as indicated by the error ‘This is silver’, not a person who does not see it *as* silver. That someone simply fails to be aware - from not grasping a distinction between a memory and a perception - that the thing in front is not silver is insufficient to prompt the act of reaching out to pick it up. It must be cognized *as* silver. Therefore, the erroneous cognition is single but, like all verbalizable cognition, complex: what is verbalized as ‘this’ is the cognition’s indicating a qualificandum, a bearer of properties, and what is verbalized as ‘silver’ is the cognition’s predication content, a qualifier that the qualificandum is presented as having. This analysis gives us, finally, the truly right view, *anyathā-khyāti*, ‘manifestation (of a qualifier) elsewhere (than where in fact it obtains)’. A causal story is indeed to be told of why a particular illusion occurs, and of how such-and-such a cognition, whose predication content does not qualify the qualificandum cognized, can be generated. Cognition is a complicated process, and the possibilities for something going wrong are numerous, depending on what is cognized, the sense organs, internal dispositions, and other factors.

Eschatology

Eschatology is the study of or doctrine about the end of history or the last things. Eschatology is a branch of Christian theology, and the term still finds its primary home in that context, but it is also used broadly to cover any theory about the end of human life or of the world.

There are many types of eschatological theory. Some of the most important are those of Plato, Vedāntic Hinduism, Karl Marx and Christianity. The contemporary philosopher of religion who makes most use of eschatology in his thinking is doubtless John Hick. There are several issues that are of interest to philosophers in the area of eschatology. Among them are such questions as whether there is good reason to believe that human life and/or history are moving towards a final end; whether personal identity problems are solvable in the eschaton *(the end-state); whether eschatological considerations can help philosophers address other philosophical problems (for example, the problem of evil); whether the very notion of disembodied survival of death is coherent; and how (in Christian theology especially) immortality of the soul and bodily resurrection are related.*

1 Types and varieties of eschatological theory

An eschatological theory can be either religious (as in Christianity) or secular (as in the classless society anticipated by Marx). But it is important to note that eschatology always presupposes a linear view of history. The common assumption of all eschatology is that human life and/or history are moving in a certain direction, towards a certain end or goal (see History, philosophy of §§1-2). Accordingly, circular views of history, or even linear views of time with no envisaged afterlife or end-state, have no eschatology.

What we might call a theory of *individual eschatology* presupposes that there is life after death for human beings and deals with their postmortem fate. The three main options for those who affirm an individual eschatology are reincarnation, immortality of the soul, and bodily resurrection (see Reincarnation; Soul, nature and immortality of the; Resurrection). What we might call a theory of *cosmic eschatology* deals with the larger issue of the goal or end towards which (so it is claimed) history is moving and with what happens at the end of history or of the world.

Plato (§13) is an example of a philosopher who argued for an individual eschatology but no cosmic eschatology. It is exceedingly difficult to combine into one coherent theory everything that Plato said in his dialogues about the soul and its life after death. Nevertheless, in both the *Phaedo* and the *Republic* he argued that the human soul, which he took to be the essence of the person, is indestructible and thus immortal. It survives death and faces judgment for its earthly deeds. Since Plato was convinced of the moral governance of the universe, he expected that this judgment would be just, with punishment for evil people and reward for the righteous. He did not dogmatize about the details of the afterlife, offering only ‘possible’ or mythic explanations. This much can certainly be said about Plato’s individual eschatology. However, there seems to be no notion in his writings of history moving towards a goal or end.

Theories of reincarnation, at least those that posit a possible final escape from the cycle of life, death and rebirth, also typically suggest an individual eschatology, but no cosmic eschatology. The Vedāntic school of Hinduism affords an example. Ultimate reality is Brahman; it is pure being or pure consciousness and is beyond all qualities. The phenomenal world is *māyā*, the realm of illusion. *Māyā* is the product of the creative power of Brahman, not through conscious acts of creation, but through Brahman’s emitting successive waves or emanations of reality. *Māyā* is unreal in the sense of not being ultimately real, of being temporary and contingent, unlike Brahman. One aspect of *māyā* is the existence of *jīvas*, individual souls that are incarnate as empirical selves. Limitless numbers of *jīvas* have always existed and are born in various bodies, both human and nonhuman. After the death of one body, they are reborn in another, a *jīva*’s station in life being a function of its deeds in previous lives.

Karma is an impersonal law to the effect that *jīvas* reap in one life what they have sowed in previous lives. The karmic imprint is carried from one incarnation to the next by what is called the subtle body. Western philosophers would call it mental; it is a body in the sense that it is part of the realm of *māyā*. It registers and transmits the moral and spiritual influence of previous lives. Through a series of lives, it is possible for *jīvas* to be purged of ignorance (*avidyā*) and evil, and to attain true self-consciousness, which is consciousness of their own essential oneness with Brahman and of the illusoriness of all differentiation (reality for Vedāntists is non-dual). If *ātman* is the

non-empirical self, the eternal and immutable spiritual reality of each *jīva*, then liberation (*mokṣa*) and escape from rebirth are achieved when one realizes that '*ātman* is Brahman'. In other words, an empirical self is an expression of a *jīva*, which is itself ultimately one with *ātman*, which is itself ultimately one with Brahman.

Karl Marx (§12) is an example of a philosopher who argued for a cosmic eschatology but no individual eschatology. Marx believed neither in God nor survival of death, but he did posit an end-state towards which history is irresistibly moving, namely increasing suffering of the workers, increasing contradictions in capitalism, world revolution, the dictatorship of the proletariat, and a final ideal society. In this society there will be common ownership of property and of the means of production; productivity will increase and prosperity will prevail; and there will be no wages, government or class structure.

Like most historical religions, Christianity posits both an individual and a cosmic eschatology. Christian eschatological notions are not easy to summarize, and eschatology is an area of great disagreement among theologians. The idea of personal survival of death arose late in the Hebrew Bible, but the hope of national and spiritual revival on the 'Day of the Lord', when God will judge the wicked, vindicate the righteous and restore the nation of Israel, was ancient. In the first century AD, the Pharisaical party accepted the idea of life after death while the Sadducees did not.

Jesus announced the end of the present age and the arrival of the kingdom of God, and the New Testament writers interpreted his life, death and resurrection as the defeat of all the forces that oppose God's rule. They also held that Jesus' resurrection from the dead is a promise of a general resurrection and of eternal life for those who believe in him. In one sense the kingdom of God arrived with the advent of Jesus; in another sense, the sense in which it arrives publicly and with power, it is postponed until the end-time. Thus Christian eschatology points to the end-time as the period when Jesus will return and the divine redemptive purposes for creation will be fulfilled. There will be a new heaven and a new earth. People will be raised from the dead and judged; the damned will live forever apart from the presence of God in hell, and the blessed will 'see God' in heaven (see Hell; Heaven).

2 John Hick on eschatology

Among contemporary philosophers of religion, John Hick has made the most sustained use of eschatology. In his earlier writings he introduced the notion of 'eschatological verification'. In response to critics such as Antony Flew who argued that theological statements like 'God exists' and 'Jesus is the Son of God' are unfalsifiable and thus without cognitive content, Hick argued that the mere possibility that such statements might be verified in some future *eschaton* (one day we might have, for example, an unambiguous experience of 'the reign of Christ in the kingdom of God') renders those statements cognitively meaningful here and now (1957: ch. 7).

Following Origen (§4) and other theologians, Hick also posits an eschatological universalism in which every human person will eventually achieve full consciousness of God and thus salvation or liberation. There is no hell, at least no permanent hell. In *Death and Eternal Life* (1976), Hick argues for a possible afterlife in which this might occur, one involving various lives in different worlds. In the end-state, Hick says, personality is retained but egoicity is transcended. Hick also uses universalism as an important element in his soul-making theodicy. Unless everyone will eventually enter a limitlessly good end-state, he says, the problem of evil cannot be solved. Hick thus holds that there can be no successful theodicy apart from eschatology.

3 Philosophical issues in eschatology

There are many issues of interest to philosophers in eschatology. Four will be briefly noted, and a fifth discussed.

(1) Perhaps the most important issue is the question of whether there is any good reason to believe that human beings will survive death and/or whether history is moving towards a final end. This question obviously cannot be answered apart from larger questions about what sort of world we live in, and whether it can be fully described in entirely naturalistic terms or whether some sort of God or divine reality exists (see God, arguments for the existence of). As far as individual eschatology is concerned, most philosophers seem to have lost interest in the classic 'proofs' for survival of death, such as those of Plato or Kant (§11). Some look to such empirical or psychological phenomena as near-death experiences, psychical research or purported memories of previous lives. But in general the project of offering philosophical arguments for or against survival of death is not nearly as popular as it once was.

(2) One of the most interesting philosophical issues related to eschatology is that of personal identity in the afterlife, whether the denizens of the afterlife will be identical to the ante-mortem persons they will apparently claim to be. Will the traditional criteria of personal identity (see Personal identity) suffice to establish that identity? If not, will 'closest continuer' or other notions less robust than identity satisfy the concerns of the religious systems in which most survival theories are embedded?

(3) Another important question is whether eschatological considerations can or should play any role in solving the problem of evil, as Hick insists that they can (see Evil, problem of §4). For Christian theodicists at least, Hick seems right. As the apostle Paul said, 'I consider that the sufferings of this present time are not worth comparing to the glory about to be revealed to us' (Romans 8: 18). Critics will respond that it is question-begging or in some other way unconvincing to 'solve' the problem by appealing to a future outcome that is hoped for but in no way assured. Theodicists like Hick can reply that it is rationally permissible and even essential that they respond to the problem of evil from the perspective of their own beliefs or those of their religious community, which may well include belief in an afterlife and eschatology.

(4) In an often-reprinted article (1953), H.H. Price argued for the coherence of the notion of a purely mental world, thus supporting the possibility of disembodied survival of death. Price posited a world of mental images (visual, auditory, telepathic, and so on) in which souls are aware of each other, live in a coherent 'world' (consisting of mental images rather than physical objects), communicate with each other telepathically, and have dreamlike (rather than bodily) perceptions of their world. According to Price, such a world may have different causal laws from our present world (for example, wish-fulfilment will be powerfully operative), but it will seem to its denizens just as real and even as 'solid' a world as ours does to us.

Some have detected problems in Price's argument. Hick, for example, notes that it is hard to combine Price's insistence on the public, non-solipsistic nature of the world he describes with his notion that the character of the world will be in large part a function of the wishes of its inhabitants (1976: 265-77). If it is a public world, sustained by telepathic contact between different individuals, how can wish-fulfilment be as potent a force in shaping it as Price suggests? Hick may well be correct here in detecting a tension in Price's account, but the problem seems solvable. And if it is solvable, then Price's main point - that disembodied survival of death is logically possible - is correct.

(5) A question relating specifically to Christian eschatology is that of the relationship between immortality of the soul and bodily resurrection. Traditional Christian theories, such as those of Aquinas, combine the two, arguing that after death there is an interim period during which we exist merely as disembodied souls, and that only later, at the end-time, will our bodies be miraculously raised by God and reunited with our souls, thus making us whole and complete persons again.

This picture now faces three quite different sorts of challenge. First, the two theories have been radically separated by the New Testament scholar Oscar Cullmann (1973). He argues that only resurrection is a genuinely Christian notion; immortality is an alien theory imported from Greek philosophy. It played no role in primitive Christian conceptions of the afterlife and ought not to be part of Christian belief today. Second, several contemporary philosophers (such as Antony Flew and Terence Penelhum) argue that the very concept of disembodied existence is either incoherent or deeply problematic. There are, however, other philosophers (such as John Hick and Richard Swinburne) who strongly defend the coherence of the concept. Third, many contemporary liberal Christian theologians (such as Hans Küng) are inclined to dismiss bodily resurrection in favour of a theory (usually only vaguely spelled out) called 'spiritual resurrection'. As with virtually all Christian theologians, their eschatological views presuppose certain views (in this case revisionist ones) of Jesus and of the reliability of the biblical witness to Jesus. They claim that bodily resurrection amounts to a superstitious and unchristian theory of resuscitation; what was raised was not Jesus' body but his person or self. On the other hand, there are contemporary philosophers and theologians who defend more traditional Christian notions of resurrection, both the resurrection of Jesus (for example, William Craig) and the general resurrection (for example, Stephen Davis).

Returning to Cullmann, he is entirely correct in differentiating immortality from resurrection. Immortal souls naturally survive death; for resurrected persons, on the other hand, survival of death occurs only because of a miraculous intervention by God. On the view of souls as naturally immortal, the human body is the intrinsically evil prison-house of the soul; on the view that bodies are resurrected, both body and soul were created good by

God, are now equally corrupt due to sin, and are thus equally in need of redemption. On the first theory, death is a friend (at least, as Plato says, to the philosopher) precisely because it means escape from the body; on the second, death is a fearsome enemy that must be defeated.

Still, Cullmann seems too hasty in rejecting any notion of immortality as unchristian. The traditional or Thomistic notion of the bodiless interim state can easily be purged of the problematic aspects that Cullmann correctly sees in Plato's theory. The survival of death of even the soul can be attributed to a gracious and miraculous act of God; it can be affirmed that both body and soul are sinful and must be redeemed; and death can still be seen as an enemy. Furthermore, the traditional notion seems to offer a way of resolving a possible tension in the New Testament concerning the time of entry into eternal life. Pauline thought especially seems committed to the idea that the general resurrection occurs at the end-time (2 Thessalonians 2: 1-15); yet Jesus said to the 'good thief' on the cross, 'Today, you will be with me in paradise' (Luke 23: 43). The solution, then, is that the thief's soul went immediately to paradise, only much later in the end-time to be reunited with his body.

Essentialism

Essentialists maintain that an object's properties are not all on an equal footing: some are 'essential' to it and the rest only 'accidental'. The hard part is to explain what 'essential' means.

The essential properties of a thing are the ones it needs to possess to be the thing it is. But this can be taken in several ways. Traditionally it was held that F is essential to x if and only if to be F is part of 'what x is', as elucidated in the definition of x. Since the 1950s, however, this definitional conception of essence has been losing ground to the modal conception: x is essentially F if and only if necessarily whatever is x has the property F; equivalently, x must be F to exist at all. A further approach conceives the essential properties of x as those which underlie and account for the bulk of its other properties. This entry emphasizes the modal conception of essentiality.

Acceptance of some form of the essential/accidental distinction appears to be implicit in the very practice of metaphysics. For what interests the metaphysician is not just any old feature of a thing, but the properties that make it the thing it is. The essential/accidental distinction helps in other words to demarcate the subject matter of metaphysics. But it also constitutes a part of that subject matter. If objects have certain of their properties in a specially fundamental way, then this is a phenomenon of great metaphysical significance.

1 Anti-essentialism

Essentialists have two basic commitments: to the essential/accidental distinction as such; and to the existence of properties of both types. Accordingly there are two main schools of anti-essentialism. 'Sceptical anti-essentialists' reject the very idea of essential versus accidental, while 'trivializing anti-essentialists' insist that all or nearly all properties fall on the same side of the line.

Sceptics typically argue as follows. Whether *x* is essentially *F* is supposed to turn on whether it is necessary that *x* be *F*. But this leads to contradictions. Is nine essentially greater than seven? Yes, because nine is seven plus two, and it is necessary that seven plus two exceeds seven. Yet also no, for nine is the number of planets, and it need not have been that the numbers of planets exceeded seven. The only way out is to admit that nothing is essentially *F* as such but only as described in a certain way. So-called 'essential' properties are really just properties entailed by some currently salient description.

What ought to make us suspicious is that similar worries can be raised about intuitively quite innocent distinctions, such as that between the constant properties of a thing - those that it always possesses - and its temporary ones. While it is always the case that seven plus two exceeds seven, for example, the number of planets was (let us imagine) once six. Described one way, then, nine is constantly greater than seven, while described another it is only temporarily greater than seven.

Here the fallacy seems clear. For the purposes of assessing constancy, 'it is always the case that the *D* is *F*' must be read *de re*: 'concerning the object which is in fact the *D*, it is always *F*' (see De re/de dicto). Read *de re*, the objector's claim that at one time the number of planets was six is simply false because nine was never six. Might not a similar response be available to the essentialist? It certainly might, unless the sceptic can convince us that *de re* modal talk is less intelligible than its temporal analogue.

Sceptics have tried, complaining that there is nothing on the modal side to match our well-developed criteria of identity over time (see Possible worlds §1). But since temporal criteria have clear trans-world implications (that a thing can evolve in such-and-such ways shows it to be capable of such-and-such otherworldly careers), the latter cannot be *too* shapeless without dragging the former into similar disrepute. Anyway, few essentialists would grant the sceptic's assumption that without trans-world identity criteria, *de re* modal discourse becomes emptied of content. If anything, content flows in the other direction; to call a counterfactual object identical to *x* is just to say that its properties are *ipso facto* properties *x* could have possessed.

Now turn to the trivializer's claim that all, or nearly all, of the properties of a thing are accidental; or else that all, or nearly all, are essential. The second idea seems to be present in Leibniz, who holds that Adam would not have existed had Peter not gone on to deny Christ some thousands of years after his death. (Even today one encounters

it in remarks such as ‘If the pistol had been equipped with a silencer, a death would have resulted, but not the same death’.) This ‘superessentialism’ is often backed by a strikingly unconvincing line of argument, namely that the identity of indiscernibles (see Identity) rules out a possible *x* differing from our actual *x* in any way. (G.E. Moore’s ‘External and Internal Relations’ (1919) contains a devastating critique.) The first idea of trivialization is far more common.

Not every property can be accidental, because it is sometimes necessary just as a matter of logic that *x* be *F*. For every *x* whatsoever, logic tells us that *x* is round if round. Since what logic tells us is necessary, ‘being round if round’ is essential to *x*. But perhaps the trivializer will try to draw the line at these ‘logically essential’ properties, counting all other properties accidental.

Such an approach will seem more trivializing than it is if one supposes that a property logically essential to one thing is thereby logically essential to everything. ‘Identity with *x*’ is the obvious counterexample; it is logically necessary that $x = x$ but not that $y = x$, so ‘identity with *x*’ comes out essential to *x* alone.

Now, though, it becomes hard not to allow additional properties as essential. Without accidental identity, for example, how can there be accidental distinctness? Apparently, then, nine, in addition to being essentially identical to nine, should be reckoned essentially distinct from seven. But to be identical to seven, another number after all, would seem to be less contrary to the nature of nine than to be an entirely different kind of thing, such as a painting or person. Once we recognize non-membership in these other kinds as essential to nine, there seems little point in refusing to count it essentially a member of its actual kind, that is, essentially a number. By this point, we have shed our former colours and taken on a modest and unassuming essentialism.

2 Grades of essential involvement

Nearly all essentialists regard at least kind-properties as essential: Aristotle is essentially human, the set of horses is essentially a set, ‘Cow’s Skull’ is essentially a painting, and so on. But it is common to go further and conceive a thing’s kind as the key to its essential properties more generally. The simplest version of this ‘priority of kinds’ doctrine maintains that (ignoring identity-properties and other such trivia) the essential properties of a *K* are, first, to be a *K*, and, second, whatever being a *K* entails. Thus while *K*s have different essences than things of other kinds, between themselves all *K*s are essentially alike.

Yet there might be reasons for allowing essential differences within a kind. Does not each set, for instance, have its specific membership essentially, and is not each painting essentially due to its actual painter? Such a view may seem at odds with the priority of kinds doctrine; but the conflict is only superficial, for we can understand a thing’s kind to dictate not the essentiality of this or that specific property, but the essentiality of its properties of such-and-such types, whatever those properties may in fact be. So, Kripke proposes that a person essentially derives from whatever gametes they in fact derive from: ‘How could a person originating from different parents, from a totally different sperm and egg, be *this very woman*?’ (1980: 113; original emphasis). Again, ‘could *this table* have been made from a completely *different* block of wood, or even of water cleverly hardened into ice…?’ (1980: 113; original emphasis). It could not, so the table essentially originated in this block of wood or one sufficiently like it.

Now that we are countenancing essential differences among conspecifics, we might wonder how deep these differences run; indeed, whether each object emerges with a uniquely identifying modal profile. By an ‘individual essence’ of *x*, let us mean a collection of properties such that

(1) necessarily, whatever has these properties is *x*, and
(2) necessarily, whatever is *x* has these properties.

The second clause asks for properties necessitated by ‘identity with *x*’, that is, properties essential to *x*. But where shall we look for properties with the further feature, demanded by the first clause, that to possess them is *sufficient* for identity with *x*? Of course, the property of ‘identity with *x*’ handles the job easily. But a property whose identity itself depends on that of *x* seems ill-suited to the task of singling *x* out. Thus our problem becomes one of finding individual essences untainted by identity-properties and similar trivia. Essentialists of an Aristotelian bent call this impossible: ‘to make clear which thing a thing is, it is not enough (*pace* the friends of logically particularized essence) to say however lengthily that it is *such*, or *so and so*’ (Wiggins 1980: 104; original

emphasis).

Opposing this pessimism are, first, the Leibnizian strategy of specifying which thing *x* is through a world-by-world catalogue of its properties and, second, Forbes' idea of identifying *x* as the unique entity of its kind originating in a certain way from certain other entities: its members if *x* is a set, its original matter if *x* is an artefact, its gametes if *x* is an organism, and so on (Forbes 1985: ch. 7).

Note that the second approach does not offer to identify objects in purely qualitative terms, but only in terms of prior objects. This is not objectionable in itself but it does leave a puzzle about items to which nothing is prior, say, coexistent eternal particles of the same kind. How will their essences differ? (Faced with a similar problem, Aquinas decided that each angel was a species unto itself.) Proponents of the first approach can say that, for each particle, there is a world where it exists all by itself. But since these worlds are not themselves distinguishable except in terms of their solitary inhabitants, this leaves us not much further ahead. Ultimately, then, the Aristotelian may have a point; at least some identity facts will have to be taken as primitive and unexplained.

3 Essential epistemology

Kant famously remarked that experience tells us how a thing is, but not that the thing could not have been otherwise. If this is true, how do we discover essential properties?

At least the outlines of an answer are set forth in Kripke's *Naming and Necessity* (1980). Suppose that the essential properties of *x* flow from its kind *K* in the following sense: *x* is essentially *F* if and only if *x* is *F* and *F* is a type of property that *K*s possess essentially if at all. Then to know *x*'s essential properties, it would be enough to know (1) its kind, (2) which types of properties things of that kind possess essentially, and (3) which properties of those types *x* actually possesses.

Can we claim access to this information? For at least many objects, it seems arguable that (2) is knowable a priori and (3) a posteriori. One knows a priori, for example, that paintings essentially derive from their actual painters, and a posteriori that Georgia O'Keeffe painted 'Cow's Skull'. As for (1) - in this case, the knowledge that 'Cow's Skull' is a painting, this involves a priori and a posteriori factors working together. Experience reveals that 'Cow's Skull' has a certain history, internal make-up and so on, and it is a priori that these features suffice to make it a painting.

4 Applications of essentialism

Apart from uses already mentioned, what is the essential/accidental distinction good for? From Descartes on, many have seen its potential as a counter to identity theses. The argument is simple. Identicals are indiscernible, so if *x* has a feature essentially that is at best accidental to *y*, then *x* and *y* are distinct. Allowing that my body is essentially a thing that takes up space and I am not, it follows that I am distinct from my body. If the tree in the quad can exist without my idea of it, then since the same cannot be said of my idea, my idea is not the tree.

Yet the argument might appear to prove too much. Imagine a statue that is always composed of the same hunk of clay, while the clay, for its part, always composes the statue. Given their overwhelming similarity, the statue and the clay might well seem identical. True, the statue is essentially humanoid in form while the clay would survive reshaping into a ball. But are we really to conclude, on the basis of such a subtle difference, that the statue and its clay are two distinct objects?

So-called 'one-thingers' suspect a fallacy of equivocation. Substituting 'the clay' for 'the statue' in 'The statue is essentially humanoid' reverses its truth-value, all right, but is this due to a change in subject matter or a change in what is said about that subject matter? Perhaps the substitution works to deflect attention from the property of having humanoid statue-counterparts to that of having humanoid clay-counterparts. That two separate properties are involved removes the need for a distinction between the objects (see Lewis 1971).

'Two-thingers' urge us to accept the distinction while rethinking its significance. If objects as similar as a statue and its clay can fail to be identical, then non-identity is not *per se* a very powerful conclusion. This makes life harder for philosophers promoting substantive forms of dualism; they must now explain what beyond mere non-identity they intend, and what they can offer as evidence beyond mere differences in essential properties. But life becomes easier for those struggling to understand the various intimate identity-like relations so important in

recent metaphysics; for instance, the relations between material objects and their constituent matter, between actions and their associated bodily movements, between mental states and the physical states that realize them, and between fine-grained events occupying the same spatiotemporal region. The last example will be developed further since it sets up one final application of essentialism, to the problem of causation.

What is the relation between the Titanic's sinking so swiftly and its sinking at all? Both events were swift but only the first, arguably, had to be so. This comes out in the fact that the Titanic's sinking might have stretched out over days or weeks (suppose that certain hatches had held) whereas its *swiftly* sinking could not have been that prolonged. Of course it is not just in this respect that the events differ. That the hatches broke was crucial to the ship's swiftly sinking, but no factor at all in its sinking as such; and we can imagine that it was the ship's sinking as such (not its sinking so swiftly) that led to the navigator's dismissal. Is this only happenstance or can we find a theory of causation capable of 'predicting' the causal differences between the events from their essential differences? A counterfactual theory looks promising since the conditions under which an event would not have occurred are visibly sensitive to its essential properties.

5 Conceptions of the essential

So far we have been understanding an essential property of *x* as a property that *x* cannot exist without. But although this is the prevailing conception of essentiality, even its advocates admit that it suffers from certain anomalies. The first and best-known concerns the property of existence. Since it is impossible to exist without existing, the modal conception extends to absolutely everything a compliment normally reserved for God, namely essential existence. The problem arises because of the way we conditionalize on existence in the definition of an essential property. Suppose then that we drop the existence condition and define the essential properties of *x* simply as the ones it must possess, regardless of whether it exists or not. This has the desired effect of eliminating essential existence for contingent beings, but at a cost: no property presupposing existence can be essential to such beings either. So, since to be human one must exist, you and I are not essentially human; hence, perhaps, not human at all.

Now to a second and deeper problem. A thing's essential properties are supposed to be the properties that make it the thing it is. But the modal conception has no way of distinguishing the properties that make *x* the thing it is from the ones it has as a necessary result of being that thing; it cannot distinguish the *conditions* of *x*'s identity from the *consequences* of its identity. This is clearest in the case of universally necessary properties such as that of 'being an element if gold', or 'being such that 2 + 3 = 5'. Neither helps make Aristotle the thing he is, but since nothing can be Aristotle without them, the modal conception reckons them essential. Now consider Aristotle's not-universally-necessary property of being distinct from the Eiffel Tower. This is not a factor in Aristotle's identity either; or, to explain what Aristotle was, we would have to mention every other object, past, present and future. Nevertheless, the modal conception calls it essential to Aristotle to be distinct from the Eiffel Tower. A final example seems decisive. To go by the modal conception, Aristotle's membership of {Aristotle} (the set whose only member is Aristotle) is essential to man and set alike. But the truth is surely different: although it lies in the nature of the set to contain the man, the man's membership of the set is not a condition of his identity but a consequence of it. No purely modal account can deliver this result; the case presents no modal asymmetries whatever, hence none for a modal account to exploit.

Troubled by these anomalies, Fine has urged a revival of the definitional conception of essence. With each object *x*, he associates a proposition $D(x)$ to function as the 'real definition' of *x*. The properties essential to *x* are those that can be assigned to it just on the basis of $D(x)$, with no help from any other source. Assuming suitable definitions, this approach allows him to resist the unwelcome essential attributions of the last few paragraphs. Aristotle's definition makes no mention of the Eiffel Tower, so it cannot pronounce on the two objects' relations. Since {Aristotle}'s definition describes it as containing Aristotle, but not the other way around, their relationship will be essential to the set only (Fine 1994).

Not every modally essential property will be definitionally essential, but there is room for debate about the converse. Suppose I make a statue out of the one hunk of clay in my studio. Then in defining the statue - in explaining what it is - I will say that it was created out of this hunk of clay. I will say this despite the fact that a distinct but sufficiently overlapping hunk would have resulted in the very same statue. (In explaining what the statue *is*, why would I mention the various objects it *could* have been fashioned from?) So, 'originating in this

hunk of clay' looks like an example of a definitionally essential property that is not modally essential. Yet it could equally be argued that since the statue did not need to originate in the given clay, originating in that clay is not a condition of identity with the statue; hence it should not be considered essential even on the definitional approach.

Disputes like this force a closer look at the phrase 'conditions of identity with *x*'. Due to a familiar ambiguity in 'condition', this can mean either the necessary *prerequisites* of identity with *x* (the properties a thing would have to have in order to be *x*) or the factors actually *constituting* its identity (the properties that *x* actually possesses by which it succeeds in being *x*). Deriving from this particular hunk of clay may not be required for identity with the statue, but it seems still to be essential in the constitutive sense. To have derived from the given clay is part of what it is, even if not part of what it had to be, to be that statue.

So we end up with three conceptions of essential property, depending on whether *x*'s essential properties are understood as (1) the necessary prerequisites of identity with *x*, (2) the factors actually constituting *x*'s identity or (3) the necessary consequences of being *x*. (3) expresses the modal conception of essentiality. (2) is a fully de-modalized version of the definitional conception. (1) lies somewhere between; it is the definitional conception but with a modal twist. Each of the three seems worthy of further study.

Eternity

The distinctive, philosophically interesting concept of eternity arose very early in the history of philosophy as the concept of a mode of existence that was not only beginningless and endless but also essentially different from time. It was introduced into early Greek philosophy as the mode of existence required for fundamental reality (being) contrasted with ordinary appearance (becoming). But the concept was given its classic formulation by Boethius, who thought of eternity as God's mode of existence and defined God's eternality as 'the complete possession all at once of illimitable life'. As defined by Boethius the concept was important in medieval philosophy. The elements of the Boethian definition are life, illimitability (and hence duration), and absence of succession (or timelessness). Defined in this way, eternality is proper to an entity identifiable as a mind or a person (and in just that sense living) but existing beginninglessly, endlessly and timelessly.

Such a concept raises obvious difficulties. Some philosophers think the difficulties can be resolved, but others think that in the light of such difficulties the concept must be modified or simply rejected as incoherent. The most obvious difficulty has to do with the combination of atemporality and duration.

Special objections have arisen in connection with ascribing eternality to God. Some people have thought that an eternal being could not do anything at all, especially not in the temporal world. But the notion of an atemporal person's acting is not incoherent. Such acts as knowing necessary truths or willing that a world exist for a certain length of time are acts that themselves take no time and require no temporal location. An eternal God could engage in acts of cognition and of volition and could even do things that might seem to require a temporal location, such as answering a prayer.

The concept of God's eternality is relevant to several issues in philosophy of religion, including the apparent irreconcilability of divine omniscience with divine immutability and with human freedom.

1 The concept

Eternality - the condition of having eternity as one's mode of existence - has been understood in more than one way. Sometimes 'eternal' has been associated with endless temporal existence (as in 'eternal life') or with beginningless temporal existence (as in the medieval debate over whether the world was eternal). In these senses the concept of eternality presents no distinctive philosophical difficulties. But there is another sense of 'eternality' in which the concept has been an issue in philosophy from the Greeks to the present. The concept was given its classic formulation in this sense by Boethius (§5), who defined it as 'the complete possession all at once of illimitable life' (*The Consolation of Philosophy*, bk V, pr. 6).

Although the interpretation of the definition becomes controversial in its details, it pretty clearly identifies four elements of eternality. First, anything eternal in the Boethian sense has life. In this sense, then, eternality could not characterize numbers, truth or the world. Next, the life of whatever is eternal is illimitable - necessarily beginningless and endless. Sometimes this element has been interpreted as attributing to whatever is eternal a mode of existence that is illimitable in virtue of being absolutely unextended (like a single instant) and only in that way without a beginning or an end. But a more natural reading and one more consonant with other things Boethius and his successors say about eternity is that it is illimitable in virtue of its infinite duration. Duration is thus the (implicit) third element of eternality in Boethius' formulation. The fourth and last is conveyed by the phrase 'complete possession all at once'. Although living temporal persons may be said to possess their life, they do not possess it completely all at once because they live out their life successively. Past parts of their life they possess no longer, future parts not yet. Consequently, whatever is eternal is also not in time. Eternality thus combines atemporality and duration. (This apparent incoherence is discussed in §2 below.)

Eternity, then, is a real, atemporal mode of existence characterized by both the absence of succession and limitless duration. Nothing in that concept denies the reality of time or implies that temporal experiences are illusory. Boethius and others who use the concept suppose that reality includes time and eternity as two distinct modes of real existence, neither of them reducible to or incompatible with the other.

Temporal events are instructively ordered in terms of the A-series - past, present and future - and the B-series - earlier than, simultaneous with, later than (see McTaggart, J.M.E.). Because an eternal entity is atemporal, its life

cannot be ordered successively in either of those series. Moreover, no temporal entity or event can be past or future with respect to, or earlier or later than, the whole life of an eternal entity, because otherwise the eternal entity would itself be part of a temporal series. But nothing in eternality's absence of successiveness entails that it cannot be characterized by *presentness*, or that an eternal entity's cognitive or causal relationship with temporal entities and events cannot be a kind of *simultaneity*. Of course, the presentness and simultaneity associated with an eternal entity could not be temporal presentness or temporal simultaneity. Taking the concept of eternality seriously involves recognizing that it introduces technical senses for several familiar words, including 'now', 'present', and 'simultaneous with', as well as the present-tense forms of many verbs.

In order to allow for real relationships between what is eternal and what is temporal it is particularly important to establish a special sense of 'simultaneous'. A relationship that can be recognized as a kind of simultaneity will of course be symmetric; but, since its relata have relevantly distinct modes of existence, it will be neither reflexive nor transitive. In this sense of 'simultaneous', each of two temporal events can be simultaneous - co-occurrent - with one and the same eternal event without being in any sense simultaneous with each other. This special sort of simultaneity has been called 'ET-simultaneity' (for 'simultaneity between what is eternal and what is temporal'). From a temporal standpoint, the temporal present is ET-simultaneous with the whole infinite extent of an eternal entity's life. From an eternal standpoint, every time is present to or co-occurrent with the whole infinite atemporal duration; that is, each instant of time as it is actually present temporally is ET-simultaneous with the one enduring present of an eternal entity, so that for an eternal entity all of time is present at once.

2 Difficulties associated with the concept

Many of the difficulties in the concept of eternality have been discussed in twentieth-century philosophical literature. The most obvious difficulty arises from the combination of atemporality with duration - the heart of the concept. Ordinarily, 'duration' means persistence through time, and the incoherence of atemporally persisting through time needn't be argued. But the philosophers who developed the concept of eternality were using ordinary terms in extraordinary ways in order to express their theoretical notion of an illimitable life possessed completely all at once. Of course, language is strained when it is stretched to accommodate things utterly outside the ordinary experience language is founded on, as in the black holes and the Big Bang of twentieth-century cosmology (see Cosmology §3). Serious attempts to show that eternity really is an incoherent concept require showing that the apparent incoherence persists when the technical interpretations of its terms are fully taken into account.

One attempt at doing just that involves taking atemporal duration as a species of extension and then arguing that any extension must be divisible and so cannot be all at once, or atemporal. The problem with such an attempt is that it uses an inductive survey of temporal and spatial extensions to reach the generalization that all extensions are divisible. But since eternity is neither temporal nor spatial, it will not be surprising if the properties attributed to extension as a result of such an induction fail to apply to what is eternal.

Still, this way of avoiding the ascription of divisibility to what is eternal seems to run into an old problem: insisting that terms cannot be used univocally of temporal and of eternal things looks like introducing equivocation into the description of eternality. Not only does 'duration' not have its ordinary sense when used of the eternal, but it is also difficult to say precisely what its extraordinary sense is. This sort of problem has become familiar in connection with discourse about God. It has often been pointed out that to use ordinary terms univocally of God and creatures is to deny the transcendence of God, but to use them equivocally masks a radical agnosticism about God's nature and activity. So discourse about God can use neither univocal nor equivocal predication (see Religious language §4).

Analogical predication is the traditionally recognized solution to this dilemma, and it is also what is needed for interpreting the description of the eternal. Atemporal duration is *analogous* to temporal duration, enough like temporal duration to make using the term 'duration' helpful, but enough unlike it to mean that the definition of '(temporal) duration' will not apply. Eternal duration is fully actualized duration, none of which is already lost or not yet gained: beginningless, endless, non-successive existence possessed completely, all at once, present entirely to its possessor - a mode of existence consisting entirely in a present that is infinite rather than instantaneous. Timeless duration might well be thought of as Plato thought of it, as the genuine duration of which temporal duration is only the moving image. Not all critics of the concept of eternity find such a response adequate, and the most persistent objections to the concept concentrate on the difficulties of ascribing duration to what is atemporal.

Because eternality in the sense at issue here is taken primarily to characterize God's mode of existence, other objections to the concept stem from combining it with traditional concepts of God. In this vein philosophers have objected that a God who is eternal could not act at all, and especially not in time. But this objection is based on a confusion. Of course, there are things an atemporal God could not do - such as remembering, or planning ahead. But not all cognitive and volitional acts require temporal location, and God could engage in those that do not. Furthermore, an atemporal God could not change the past or foreknow the future. Such actions, if possible at all, would require a temporal location, without which there can be neither past nor future. Still, eternal God, present at once to each temporal instant in its temporal presentness, could in the eternal present directly affect events that are past with respect to us and be directly aware of events future with respect to us. He could also act in time. He could, for example, will timelessly that something occur or come into existence at a particular time. By the same token, he could also do things that might appear to require a particular temporal location, such as answering a particular prayer. Because both the time of the prayer and the time at which the answer to it occurs are ET-simultaneous with the whole of eternity, an eternal God could be aware, timelessly, of a prayer prayed at one time, willing (ET-simultaneously) that the answer to that prayer occur at a later time.

Finally, some critics suppose that if God is eternal and creatures are temporal, then God could not be directly aware of creatures or interact with them directly and immediately as he is traditionally said to do. Such criticisms must presuppose that for one being to interact directly with another, the two must share a mode of existence. But traditional theists are already committed to rejecting this presupposition as regards space. God is traditionally described as non-spatial and thus as not sharing with creatures a spatial mode of existence, and yet that difference in modes of existence is generally thought to be no obstacle to God's being directly aware of or directly interacting with his creatures. If the presupposition is false as regards space, however, it is hard to see why it should be accepted as regards time.

3 The history of the concept

The earliest indisputable appearance of the concept of eternity is in Plato's *Timaeus*. Parmenides' description of the mode of existence of Being, or the One, in his *Way of Truth* is much older, but scholars disagree over whether Parmenides intended to ascribe atemporality to Being (see Parmenides §3). Whatever Parmenides meant, what Plato says about eternity is in several respects just what Parmenides says about Being's mode of existence, and to that extent at least Parmenides may be thought of as the inventor or discoverer of the concept of eternity.

Many scholars believe that Aristotle rejected Plato's notion of eternity, although there is also some textual evidence suggesting that, on the contrary, he accepted and made use of it in describing the life of the Prime Mover. Whether or not Aristotle himself accepted the concept of eternity, it is indisputable that the concept came into medieval philosophy through the Platonic rather than the Aristotelian tradition. Plotinus (§4), for instance, has a well-developed concept of eternity, and in *Enneads* III 7 he stresses the importance of duration in the concept. Boethius seems to have based his definition of eternity on the one Plotinus develops.

Augustine (§8), who was even more clearly in the Platonic tradition than Boethius was, understood and accepted the concept of eternity, which plays a significant part in two of his most important works, the *Confessions* (bk XI, ch. 11) and *The City of God* (bk XI, ch. 21). Like Boethius' formulations, Augustine's views of eternity were an important influence on later medieval philosophy.

In the Middle Ages, the concept of eternity was widely used and discussed. It can be found, for example, in Anselm's *Monologion* (ch. 24) and *Proslogion* (ch. 13), where it seems taken for granted, as a standard part of traditional theology. But it received its most sophisticated development in the work of Aquinas, who discussed and employed it in several of his works (for example, *Summa theologiae* Ia, q.10). After Aquinas, although many medieval philosophers and theologians continued to hold that God is eternal, they did not always mean by 'eternal' what Boethius (and Aquinas) had meant by it. Duns Scotus, for example, seems to have held that God's eternality is not co-occurrent with all of time.

In the modern period, with the rejection of the medieval synthesis in theology, the notion of eternity, in the special sense at issue here, was largely abandoned. Hobbes is still aware of it in the Boethian sense '*as a permanent now*' (1680: 435), but Locke, for example, takes eternity to be just an infinity of temporal duration: 'By being able to repeat any such *Idea* of any length of time… and add them one to another, without ever coming to the end of such

addition… we come by the *Idea* of *Eternity*' (1689, bk II, ch. 14).

4 Applications of the concept to issues in the philosophy of religion

Applying the concept of eternality makes a significant difference in considering various issues in philosophy of religion. Here we will concentrate on just two of the most important: omniscience and immutability, and foreknowledge and free will.

It has been argued that omniscience and immutability, two traditional divine attributes, are not compossible. An omniscient knower always knows what time it is (or precisely what is going on) now, and any knower who always knows what time it is now is a knower whose knowledge is always changing. Consequently, a knower could be omniscient and mutable, or immutable and not omniscient, but there could not be an omniscient, immutable knower (see Immutability).

This argument presupposes that knowers are temporal. If omniscient God is eternal, however, the argument becomes more complicated. For example, in the claim that an omniscient knower always knows what time it is now, 'now' and the present tense of 'knows' can each be read as indicating either the temporal or the eternal present, thus allowing for four different interpretations of the claim. Not all of those interpretations make sense; for example, 'An omniscient knower always knows in the eternal present what time it is in the eternal present' incoherently attributes time to the eternal present. The most reasonable interpretation of the claim, on the supposition that the omniscient knower in question is eternal, is that the knower always knows in the eternal present what time it is in the temporal present. But on that interpretation it is much more difficult to show that such a knower could not be immutable.

Even if we suppose that the indexical 'now' is ineliminable, that there is an absolute temporal present as distinct from a present that is merely relative to some particular temporal entity, it is not clear that an eternal God could not know what time it is without constantly changing. On the view that the whole of eternity is ET-simultaneous with each temporal event as it is actually happening, an eternal omniscient knower will know all the events actually occurring at a particular time as well as the temporal location of that time and its being experienced as present by temporal entities at that time. Such a knower will also know that from the standpoint of eternity every temporal event is actually happening. There is nothing further for an eternal entity to know about what time it is now, for either the eternal or the temporal now; and nothing in what it does know requires constant change or change of any sort. Thus, while the argument may show that no temporal knower can be both omniscient and immutable, it does not make its case if the omniscient, immutable knower is eternal.

Arguments that knowledge of future contingent events is irreconcilable with human freedom depend on the notion of *fore*knowledge, on someone's knowing ahead of time what someone else will 'freely' decide to do (see Omniscience §§3-4). On the face of it, then, the concept of eternity provides a solution to the problem of foreknowledge and free will, as Boethius maintained in introducing the concept. An eternal omniscient knower will be eternally aware of *all* contingent events as they are occurring, including those that occur in the temporal future, but he will not *fore*know them, since nothing eternal can be earlier than anything else. Consequently, arguments purporting to show that foreknowledge and free will are incompatible will not apply to eternal omniscient knowledge, which is evidently compatible with human free will.

But some philosophers have thought that eternality nonetheless fails to provide a solution to the problem of divine knowledge and human freedom, because the fixity and infallibility of divine knowledge seem enough by themselves to make God's knowledge of future contingents incompatible with free will. 'God knows in the eternal present that Paula mows her lawn in 2095' entails that Paula mows her lawn in 2095, and so God's eternal awareness of a future event seems to have the result that the event is inevitable *now*, before the event occurs, in a way incompatible with Paula's freedom of action. Consequently, the concept of eternity seems after all unhelpful for resolving the apparent incompatibility between divine knowledge and human freedom.

The idea of this line of argument is that a proposition such as 'God eternally knows that *p*' (where *p* is of the form 'Paula mows her lawn (at some date future with respect to us in the present)') entails 'It is now the case that *p*'. That is why eternal knowledge is supposed to have the result that the future is somehow fixed and inevitable now. But is there such an entailment? 'God eternally knows that *p*' does entail *p*, and *p* does seem equivalent to 'It is now the case that *p*'. But is it equivalent in a context involving eternality? In that context, God knows that *p* in

virtue of being ET-simultaneous with the future events he is eternally aware of. In that context, furthermore, it is also true that God's knowledge that *p* is ET-simultaneous with the temporal now. That is why we can appropriately say such things as 'It is now (in the temporal present) true that God eternally knows that *p*'. But, as has already been pointed out, ET-simultaneity is not transitive. From the facts that the state of affairs that *p* is ET-simultaneous with eternity and that eternity is ET-simultaneous with the temporal present, it does not follow that it is *now* the case that *p*. Therefore, while it is true that God's knowing that *p* entails that *p*, the relationship between time and eternity is such that God's knowing that *p* does not entail that it is *now* the case that *p*. Hence, it seems that the concept of eternity can constitute the basis for an adequate solution to the problem of foreknowledge and free will.

Eternity of the world, medieval views of

The problem of the eternity of the world was much debated in Western philosophy from the twelfth through the fourteenth centuries, but its history goes back as far as Philo of Alexandria and the Church Fathers. The principal topic of controversy was the possibility of a beginningless and yet created world. The arguments that fashioned the medieval discussion rested upon assumptions concerning the concepts of eternity and creation. In addition, the issue of eternity intertwined with discussions of the relationship of God to creation, with proofs of the existence of God, with the nature of the material universe and with the nature of infinity. Some of the most ingenious ideas in these debates were obtained from pagan Greek, Islamic and Jewish traditions.

1 Early stages

According to Judaeo-Christian tradition, based in particular upon the opening words of Genesis ('In the beginning God created the heaven and the earth'), the universe had a beginning. From the fourth century onwards, however, Christian thinkers had to take into consideration accounts from antiquity, transmitted by authors such as Augustine and Boethius, according to which the existence of the material universe (*mundus*) was 'from eternity' (*ab aeterno*), that is, beginningless.

In its early stages, the medieval discussion of the eternity of the world was preoccupied with two types of questions, one asking whether the world had existed from eternity and the other examining the concept of eternity and its relation with time. In general, 'time' (*tempus*) was understood to imply having both a beginning and an end, and perpetuity (*aevum*) involved a beginning but not an end, whereas 'eternity' (*aeternitas*) had neither beginning nor end. 'Eternity' in this sense was understood as a temporal notion, meaning 'infinite temporal extension'. However as Boethius pointed out in *De consolatione philosophiae (The Consolation of Philosophy)*, 'eternity' could also be taken as atemporal. This conception of eternity, sometimes called 'eternity proper' by later authors, introduced the notion of timelessness within the notions of 'all at once' (*tota simul*) and of 'life', and referred to God's mode of existence.

Medieval thinkers all agreed that the universe was not coeternal with God. They were divided, however, over the question whether the universe had always existed in a temporal sense, and over how this question should be understood in the first place. Using a distinction derived from Augustine in *De civitate Dei (The City of God)* and *Confessiones (Confessions)*, many medieval thinkers would observe that the world was created *together with* time, and in this sense had *always* existed: there was no past at the time of creation.

In the early thirteenth century, the discussion of the eternity of the world was raised to a higher level. Three events contributed to this. First, the Fourth Lateran Council (1215) declared the temporal beginning of the world to be an article of faith. Second, around that same time the *Sentences* by Peter Lombard, which included a statement (Book 2, distinction 1) about the world's eternity, became an official textbook in the faculty of theology. Third, the translation into Latin of Aristotle's books on natural philosophy (*Libri naturales*), especially *Physics* VIII, brought medieval thinkers in the arts faculty into routine contact with arguments proving the eternity of motion and generation (see Aristotle). Aristotle's views on eternity, especially the question whether he had intended to prove the beginninglesness of the world, became an issue of debate that culminated in the condemnations of 1270 and 1277 by Bishop Etienne Tempier (see Aristotelianism, medieval). Aristotle's views were perceived through the interpretations offered by Averroes' *Commentary on Aristotle's Physics* and Maimonides' *Guide to the Perplexed*, works that had also been translated recently into Latin (see Averroism; Ibn Rushd; Maimonides, M.).

The most important result of these events was that the issue to be debated came into sharper focus: could the world have been eternal, if God had so willed? In other words, must the beginning of the world be accepted as an article of faith, or can it also be proved by (demonstrative) arguments? In this way, the issue of the eternity of the world helped to determine the position philosophers held with regard to the relation between faith and reason.

2 The two sides

The various conceivable ways of responding to the question of the eternity of the world can be reduced to the following two positions. One group of thinkers, of whom Bonaventure is the archetype, claimed that it could be demonstrated that the world began to exist. Other adherents of this position were Matthew of Aquasparta, Henry of

Ghent, John Pecham, Richard of Middleton, Peter Aureol, William of Alnwick, Henry Totting of Oyta and Marsilius of Inghen. The demonstrations hinged on two basic assumptions concerning creation and eternity.

The Christian view had come to be that God had created the world where before there had been nothing: in other words, creation from nothing. In an argument that goes back to Richard of St Victor, it was maintained that since creation from nothing (*ex nihilo*) is a transition from non-being (*nihil*) to being, non-being necessarily precedes being. Hence, creation necessarily implies a beginning in time. In sum, creation 'from nothing' was understood as creation 'after nothing' (*post nihil*).

Furthermore, an eternal world was conceived to imply the existence of an infinite series of past events. The contradictions that allegedly arose from this assumption were considered reasons why an eternal world is impossible. Most of the arguments were drawn from Aristotle's widely accepted theory of the infinite, but were here employed in a new context to substantiate the un-Aristotelian conclusion that the world is not eternal but had a beginning. In particular, the following generally accepted Aristotelian rules were considered to be violated by the idea of a beginningless world: first, that it is impossible to add to the infinite; second, that it is impossible to traverse what is infinite; third, that it is impossible for the infinite to be grasped by a finite power; and fourth, that it is impossible that there be simultaneously an infinite number of things. In addition, the theory of a possible eternal world seemed to clash with self-evident principles such as that the whole is greater than the part (John Pecham) or that, since the infinite is *infinite*, one infinity cannot be greater than another, or that there is no order in the infinite because there is no first element (Bonaventure). Some of these alleged contradictions had already been pointed out by John Philoponus in his *De aeternitate mundi contra Proclum (On the Eternity of the World Against Proclus)* and had circulated among Arabic authors such as Algazel in his *Metaphysica* before they were transmitted to the Latin West (see al-Ghazali; Islamic philosophy: transmission into Western Europe).

Another group of thinkers, including Siger of Brabant, Boethius of Dacia, Thomas Aquinas, Giles of Rome, Godfrey of Fontaines, William of Ockham, Henry of Harclay, Thomas of Wylton and Thomas of Strasbourg, argued that the universe could have existed from eternity. In part, their argumentation rested on the rebuttal of those arguments that the proponents of a demonstrable beginning had invoked to refute the possibility of an eternal world. They concluded that since the beginning of the world could not be *demonstratively* proved, the universe could have existed without beginning to exist.

Proponents of the possibility of a beginningless universe interpreted creation out of nothing as creation not out of anything, that is, not out of any independently existing matter. Creation was understood as a relation of causal dependence of creatures upon God, and in this interpretation the status of being a creature was not necessarily inconsistent with being beginningless. The argument that the universe depends for its existence upon a superior principle that is not prior in time but prior in the order of things can be found in Avicenna's *Metaphysica*, and was at the heart of Aquinas' rebuttal of Bonaventure's interpretation of creation from nothing (see Aquinas, T. §9; Ibn Sina §4).

The infinity arguments in favour of a beginning were considered off the mark by the proponents of the possibility of an eternal world. With regard to the traversal argument, for instance (that is, the argument that if the world had always been, an infinite past time would have been traversed), they emphasized that the traversed infinite time was a successive and not a simultaneous infinity, and hence, that the contradictions that seemed to follow from the premise of an eternal world were not pertinent. There will always be only finitely many past days between this and any past day. A beginningless world does not imply that any past day was infinitely remote from this day.

In general, the adherents of a possible beginningless world held the same Aristotelian views on the infinite as their opponents. They disagreed only over the kind of infinity that was involved in a possible eternal world. Henry of Harclay was an interesting exception. He agreed with his opponents that a possible eternal world would entail an *actual* infinity, but he denied that the conclusions that followed from this stance were contradictory. Harclay argued that the infinite can be traversed, that it can be exceeded, and that not all infinites are equal (see Infinity).

Ethical systems, African

Ethical thought in sub-Saharan Africa grows largely out of traditions that are communalistic, not based in individual consent, anti-universalizing, naturalistic, and humanist. Within such thought, the general vocabulary of evaluation, like such English words as 'good' and 'bad', does not strongly differentiate between narrow moral assessments, on the one hand, and technical or aesthetic evaluation on the other. This is true of places where Islam has been present for many centuries. The substantial exposure, in the colonial and postcolonial periods, to European moral ideas (both through various forms of Christian missionary evangelism and as a result of contact with secular moral and political traditions from elsewhere), along with the changes produced by the modern economy, have produced a wide range of ethical ideas. However, the residue of precolonial ethical theory remains the most distinctive, if not always the most important, component and is the main topic of this entry.

1 Defining the subject matter

Sub-Saharan Africa has a wide range of varied cultures. A standard audit (Greenberg 1970: 25) shows that more than one thousand languages are spoken on the continent. It is made up of more than fifty modern states which include peoples descended from hundreds of earlier societies, ranging, by degrees of political organization, from the hunter-gathering King Kung of central southern Africa, who were without a ruler, through to the hierarchical states of Buganda in the east and the Yoruba and Asante in the west, to the Islamic kingdoms, emirates and sultanates of the Sahel and northwest Africa.

Most contemporary sub-Saharan African cultures have grown out of interactions between the so-called 'traditional' systems of thought of these earlier societies, on the one hand, and Christianity, Islam and the many influences of the extensive colonial administrations of modern European and US cultures, on the other. Such colonial rule, which spanned more than a century, continued until the 1970s. Ethical theory in the Maghreb (the largely Arabic-speaking region of north Africa, which has been part of the literate Islamic world for more than a millennium), deserves separate consideration in the broader context (see Ethics in Islamic philosophy; Islamic philosophy). For similar reasons, Ethiopia's literate philosophical traditions are best considered separately (see Ethiopia, philosophy in). Contemporary moral philosophy in universities is largely an extension of ethics in the colonial metropolitan cultures, more particularly of the UK and France (see African philosophy, Anglophone; African philosophy, Francophone). The ethical traditions of white settler populations in southern Africa are continuous with those of their European ancestors. This entry deals generally with those sub-Saharan African traditions that remain.

2 Traditional cultures: general features

To begin with traditional cultures, sociological and anthropological accounts suggest a number of generalizations about the ethical dimensions (in the broadest sense of practical reason) of their modes of thought and behaviour. A number of formal features related more to the kinds of moral systems there are, and less to the particular ends or values they endorse, must be considered.

First, it is widely agreed (Danquah 1944; Mbiti 1969) that these earlier societies were essentially *communitarian* or *communalistic* in their ethical ideas. This means that they held (like many pre-modern societies elsewhere) that prerogatives of rights to land use and property inheritance, for example, inhere in various corporate groups, such as families, lineages, villages and societies, rather than in individuals. These societies also maintained that the flourishing of corporate interests were superior to the projects of individuals. Thus, property rights - the claim to exclusive use of an area of land for farming for a period of time - were assigned by chiefs or kings in many cultures to lineages. The head and senior members of each such group would allocate responsibilities and a share of the crop to members of the group and would manage profits from sales or exchanges to cover the needs of individual members. Marriage and the attendant obligation to raise and support children would be a relationship between families in which control of children and their obedience often belonged to the family of one spouse. This was symbolically acknowledged by dowry payments for a future bride.

A second significant aspect of traditional ethical thought relates to the extended family or clan. This form of moral thought permits someone, the agent, to treat someone else, the patient, in a certain manner because the two are

related, not because the patient has particular qualities or needs, for example, I might give shelter to someone 'because she is my kinswoman'. This produces a structure of thought that is, in a sense, *anti-universalizing*. The reasoning behind it is historical as well as indexical and relates to the agent's conviction that the patient can be treated in a certain way: 'because she's my kinswoman', although this is not consonant with some understandings of the Kantian demand for universalizability (see Kantian ethics). (However, it is possible to defend partiality towards, for example, one's close kin as a universalizable principle. It is a familiar idea in European societies that obligations to a parent or sibling should not depend on their intrinsic attributes: Europeans and Americans do not normally suppose that the reason we should care more for our siblings than for strangers is that they have general features that make them abstractly more deserving.) Such reasons for anti-universalizability are independent of the character and needs of the patient, and do not arise out of either obligations created through consent whose model is the contract in liberal political theory (for example, Hobbes, Locke and Rawls) or reciprocation (which might account for obligation) to those who bore and brought one up. This range of obligations, rooted in unchosen relationships to people from whom one has received nothing, is much more extensive in traditional Africa than in Europe or the USA.

In matrilineal societies, for example, the Akan of Ghana and the Ivory Coast, children 'belong' to their mothers' families, which are headed ideally by a maternal uncle or great-uncle. In patrilineal traditions, for example, the Yoruba, the child 'belongs' to their fathers' lineage, which is headed ideally by a father, paternal uncle or grandfather, although these are not the only forms of affiliation known in Africa. These differing ideas of kinship have profound consequences because they determine the range of familial obligation and define who retains custody of the children after divorce. At this point, relationships enter the anti-universalizing range of the indexical reason mentioned earlier: 'because they are my kin'.

A third aspect of traditional ethical thought deals with traditional religious ideas. These were *naturalistic*, conceiving of gods, spirits and ancestors as continuous with and continually operative within the natural world. These ideas did not make a sharp ontological distinction, of the kind central to Christian and Platonist thinking, between a realm of spirit and a realm of matter. Spiritual beings were supposed to be concerned with the flourishing of specific groups of people of certain places or lineages. Because of the centrality of the prescriptions of various spiritual forces in shaping behaviour, the separation of moral principles from principles of prudence is not always easy in such a setting. (Plato's discussion in the *Euthyphro* (*c*.386-*c*.380) of whether an act is right because the gods love it or they love it because it is right, raises an unanswerable question (see Plato §2).) On the one hand, it seems clear that traditional peoples felt obligations to and wished to help others for reasons other than the spiritually-underwritten sanctions associated with not doing so (in the same way that most people do not commit murder simply because they know they would be punished if they did). On the other hand, certain proscriptions, of incest for example, that might be thought of as moral in some European societies, seem to have derived from beliefs about the consequences, as when the Azande understood leprosy to be caused by incest.

Many areas of life, such as food preparation, ritual practice in association with cults for spirits and ancestors, and everyday contact with others, generally involved the observance of taboos, for which the sanctions were often misfortunes, like hunting accidents, disease, or a failed crop visited upon an individual or the group to which they belonged. The avoidance of harm of this type was apparent in practical reasoning. Rarely was there an articulated notion of doing right that was distinct from doing what was appropriate and conformed to custom and prudence so that no taboos were violated. Indeed, one of the highest terms of commendation for conduct in many African societies was also used to describe both physical beauty and the aesthetic appeal in artefacts. Thus, in Twi, an Akan language, *fé* refers to physical beauty in people, to a well-made artefact and to commend good behaviour. A common criticism of a child's behaviour would be that it is not *fé* (see Akan philosophical psychology).

Fourth, there is often no clear distinction between moral vocabulary and aesthetic or technical commendation. This reflects the low degree of linguistic division of labour within most pre-literate communities.

A further consequence of regular involvement with spirits of lineage and place is that, in the majority of cultures that recognize a high god associated with the heavens, this god is a *deus remotus* whose interest in peoples' affairs is minimal. The notion that one's conduct should be aimed at affecting an afterlife is unusual and concern for affairs after one's death focuses on questions of one's descendants performing cultish acts for their ancestors to conserve their memory. Such systems of thought are thus *anthropocentric* or *humanistic*, centring on the

contemporary concerns of human beings, including ancestors (who are always with their kin), rather than on otherworldly considerations.

3 Traditional cultures: ethical education

The transmission of ethical ideas from one generation to the next in pre-literate societies was accomplished by counsel and correction, as well as in other important ways. In many cultures young people underwent periods of education removed from the community prior to the transition to adulthood. In these periods ideas about behaviour appropriate to one's gender and status, notions of what kind of person is worthy of respect, and conceptions of one's duties to others (including ancestors and other nonhuman spirits) were often inculcated.

It was common to recount the history (rather than the myth, as in contemporary usage myth connotes fictional status and these narratives are usually presented as true), of one's own people in terms that underwrote existing social arrangements. Ritual enactment of these histories provided a reinforcement for the broadly ethical understandings they underwrote. Another major source of moral instruction was through the various forms of *orature*, the verbal art that corresponds to the literature of literate societies. Among the most important of these are the folktale, a story told as fiction often with an Aesopian moral, and the proverb, a shorthand reference to history and the folktale. Proverbs have been seen as evidence of the moral notions of earlier African societies. Many of those who have written on this subject, including J.B. Danquah (1944), have relied on their interpretation to deduce traditional moral, and sometimes metaphysical, views. This process has its dangers: the interpretation of proverbs is a matter of context. In English, for example, it is easy to come up with two proverbs that might sound contradictory: 'more haste, less speed' and 'a stitch in time saves nine'. Which one is appropriate depends on whether the context refers to being timely or being careful. To infer from the first of these proverbs that UK culture values care over punctuality would be an error. Analogous mistakes have been made by observers interpreting African proverbs.

In African traditions the interpretation of proverbs is a difficult matter. Indeed, one Akan proverb says: 'if we tell a fool a proverb, we explain its meaning to him'. Many proverbs are less obvious in their application than the few with which most Europeans and Americans are familiar, because the language is densely figurative. A typical Akan proverb says: 'The drongo (bird) says: if he had known that the palm nuts were going to ripen, then he would not have married the raffia palm with a twisted leg'. Any contextual application of this proverb requires knowledge of the two plants in question: they are both palms, but one produces a valuable oil, while the other produces less valuable fibres. The knowledge that, before a certain stage of development, it is not obvious which is which, is also required. With this knowledge, it might be grasped that, in a particular context, the proverb was being used to express regret at having made the wrong choice in a situation of insufficient knowledge. In this context, the proverb could be said to be analagous to: 'more haste, less speed'. However, it would be wrong to infer that Akan culture values caution over efficacy. In fact, more can be learned about cultural values by exploring a proverb's presuppositions, than by the message it communicates.

There is an Akan proverb that says: 'when your child cheats your co-wife's child, it is not good; but when your co-wife's child cheats your child it is also not good'. It is often used in circumstances where the UK proverb, 'do as you would be done by', might be invoked. This proverb is used to make a point unconnected with marriage or family life and presupposes that men may have more than one wife at a time, that there is likely competition among co-wives and that this is something to be avoided. These presuppositions are communicated to young people as they grow up through the contextual and didactic use of such proverbs.

Proverbs are, therefore, an important source of ethical ideas in many cultures in Africa. As a result, the careful analysis of proverbs, especially where the analyst deals with their presuppositions, can reveal a culture's values.

4 Comparisons with 'modern' societies

In terms of content, there is less similarity among African traditions than at the level of the abstract formal features catalogued in §§2 and 3. The communitarian and anti-universalist character of ethical thought means that in most traditional African systems of ideas, public questions of practical reason, for example, in courts or in family decision making, rarely focused on the enforcement of individual rights. Instead, they concentrated on individual needs and a concern for corporate harmony. These tendencies remain in the areas where the influences of

modernity (in the form of contemporary critiques by African intellectuals, of world religions and of Euro-American ideas), have not percolated. This is in contrast to formal juridical practice in most modern societies (including the modern sectors of most African states).

Another major contrast is with the central questions of propriety, reputation and status in practical reasoning. This is striking because in Euro-American culture, at least since the Enlightenment, such questions are related to the surface of action and a concern with them is seen as superficial in ways that contrast with genuine moral concerns.

In Akan cultures the notion of *animuonyam*, which comes close to the meaning of 'respect' or 'honour', plays a central role. The possibility of losing respect is very troubling for those who have it. (Well-known Akan proverbs such as the following show that respect is not something that belong to everybody: 'father soul and father slave Kyereme, neither of them has any respect'. This means that whatever you call him or her, a slave is still a slave.) But *animuonyam* is not just related to being thought well of: it is a matter of meriting a high opinion and being seen to merit it. One way of earning respect is by providing generously for one's fellow citizens through acts of munificence or serving one's country well in warfare.

A familiarity with European or Asian moral philosophy begs the question of how public ethical discourse relates to the inner language of private decision. The difficulty in understanding this relationship stems from the fact that access to such information in those cultures is a consequence of literacy. In pre-literate societies there is no record of ethical views except through the collective sphere of oral traditions, neither are there generic conventions, such as the confession (on the model of St Augustine), or the protestant diary (as the record of an individual conscience) to provide models of organized reflection on questions outside the public sphere. More than this, central genres such as the novel provide us with models of interiority in moral life that do not occur in the major genres of oral literature. To the extent that a nuanced language of private moral reflection, distinct from the discourse of collective decision making, is the product of the kind of privacy made possible through the conventions that constitute genres of writing such as autobiography and the novel, it can be said that there is no such private morality in the pre-literate cultures of precolonial Africa.

All of these latter facts lead anthropologists to speak of cultures of (external) shame as opposed to (internal) guilt. In using such a classification, it is important to remember that shame, like guilt, requires a person to share the values that they have failed to live up to, rather than simply incurring embarrassment. Therefore, it would be misleading to think of African cultures without developed discourses of individualized (or private) morality being governed by the notion that it is only what is known publicly that is of any real ethical significance. In Asante, it is said that the man whose wife has had intercourse with another must be paid adultery fees even if intercourse occurred in a dream. This is because, in the Akante culture it is understood that dreams reflect the real experiences of one's *sunsum* and the idea that the dream is private does not exist. Thus, if a man dreams of intercourse with a woman she is assumed to have dreamed of intercourse with him. It is difficult to see how such a rule would come into being in a culture where people thought that what others did not know was of no ethical significance (see Akan philosophical psychology).

The distinction between what I know and what others know is less crucial in cultures where everyone is supposed to be the subject of continuous surveillance by spirits of various sorts and where forms of divination and spiritual vision may allow others to discover what I have done by means other than witnessing or hearing about it.

A final difference, which is as a result of the lack of models of self-reflection provided in the major modern literary genres, is that certain moral ideas, such as the modern notion of authenticity, do not appear to have been present in most African moral traditions. There are notions of behaviour appropriate to one's status or role, and notions of honesty that come close to the idea of sincerity. However, the idea that a person can truly be defined as one thing or another beneath the masks that convention and ascribed status impose, is foreign. Instead, there are notions of destiny or fate. For example, in many west African traditions, along the whole of the Guinea coast, there is an idea that people are offered or given a fate by a high god before entering the world, and that this prenatal message shapes their life on earth. It is worthy of note that, the contrasts between African ethical ideas and those of modern Europe and the USA, do not necessarily distinguish African ethics from those of other traditional peoples who are outside the areas of influence of the literate ethical culture of the monotheistic world religions.

5 Contemporary trends

Against this background, it is possible to understand the ethical crises associated, on the one hand, with the growth of literacy, the development of the African novel, and access to Western literary forms, and on the other, with urbanization and the growth of commodity production and wage labour. Each of these changes contributes to undermining the compatibility of traditional ethical ideas of kinship and community and contemporary practical life. The problem of political corruption in many African states has arisen in part from the fact that state officials in the modern sector are paid salaries intended to support a family unit closer to a Euro-American nuclear model. These officials inherit obligations to corporate groups, such as lineages and places of origin, that they cannot sustain. Similarly, the question of nepotism or tribalism in the state bureaucracy should be seen in the context of a conflict between formal rights-based notions of the role of state agents and traditional corporate obligations.

As far as sub-Saharan ethical discourse is concerned, there is evidence of the influences of Islamic and Christian theory, as well as Marxist and liberal political and moral ideas introduced through European colonial education. These latter secular traditions are not too different from their Euro-American counterparts, although Marxist revolutionaries in Africa, such as Amílcar Cabral have shared with Mao Zedong the problem of reshaping the ideas of Marx and Engels for predominantly nonindustrial societies.

With regard to major religious traditions, the contrast between traditional and contemporary ideas is less striking in Islamic areas. This is because, in many parts of sub-Saharan Africa, Islam was well-established before the period of European colonialism and existed for a long period as a literate tradition alongside the popular culture of a largely nonliterate populace. As a consequence, there was a mutual accommodation of Islamic ideas and the ethical thought of the pre-Islamic cultures into which they were introduced. It is said, therefore, that African Islam is highly syncretic, melding with local traditions in the various places it has been established. Just as Islam in other parts of the contemporary Muslim world has developed new secularizing traditions and new forms of fundamentalism, so has Africa. Secularization has tended to be the response of a literate intelligentsia with substantial familiarity with European culture, while fundamentalism has more of a popular, although literate, base. A consequence of the increasing flow of information through broadcast media and literacy, is that public ethical discourse in sub-Saharan Islamic Africa has grown closer to that of the rest of the Muslim world than it has been since the early period of African Islam.

The effect of Christianity has been to challenge the content of traditional ethical thought in many areas, such as objections to polygamy and caste-like hereditary status systems, and to appeal to ancestors and other spirits. (This latter conflict is less distinct because of the strong tradition of reference to saints, angels, devils and other ‘principalities and powers’ in European and north African Christian traditions whose spirits resemble African ones.) Furthermore, Christian otherworldliness and individualistic notions of merit and responsibility (deriving from contemporary economic relations) have penetrated many societies. It is reasonable to assume that the ethical thought of most contemporary African Christians is closer than it may appear to that of the precolonial period, especially in its communalism. To the extent that African Christians participate in formal literate ethical discourse, they do so within contemporary traditions that belong to European Christianity, with the exception of Coptic churches in Egypt and Ethiopia.

Ethics

1 Ethics and meta-ethics

What is ethics? First, the systems of value and custom instantiated in the lives of particular groups of human beings are described as the ethics of these groups. Philosophers may concern themselves with articulating these systems, but this is usually seen as the task of anthropology.

Second, the term is used to refer to one in particular of these systems, 'morality', which involves notions such as rightness and wrongness, guilt and shame, and so on (see Rectification and remainders). A central question here is how best to characterize this system. Is a moral system one with a certain function, such as to enable cooperation among individuals, or must it involve certain sentiments, such as those concerned with blame (see Morality and ethics; Moral sentiments; Praise and blame; Reciprocity)?

Third, 'ethics' can, within this system of morality itself, refer to actual moral principles: 'Why did you return the book?' 'It was the only ethical thing to do in the circumstances.'

Finally, ethics is that area of philosophy concerned with the study of ethics in its other senses (see Ethics in Islamic philosophy). It is important to remember that philosophical ethics is not independent of other areas of philosophy. The answers to many ethical questions depend on answers to questions in metaphysics and other areas (see Aesthetics and ethics; Metaphysics; Pragmatism in ethics). Furthermore, philosophers have been concerned to establish links between the ethical sphere of life itself and other spheres (see Art and morality; Law and morality). Some philosophers have, for philosophical reasons, had doubts about whether philosophy provides anyway the best approach to ethics (see Theory and practice; Wittgensteinian ethics). And even those who believe philosophy has a contribution to make may suggest that ethical justification must refer outside philosophy to common sense beliefs or real-life examples (see Examples in ethics; Moral justification).

A central task of philosophical ethics is to articulate what constitutes ethics or morality. This project is that of meta-ethics. What is it that especially constitutes the moral point of view as opposed to others? Some argue that what is morally required is equivalent to what is required by reason overall, whereas others see morality as providing just one source of reasons (see Practical reason and ethics). Yet others have suggested that all reasons are self-interested, and that concern for others is ultimately irrational (see Egoism and altruism). This has not been seen to be inimical in itself to the notion of morality, however, since a moral system can be seen to benefit its participants (see Contractarianism; Decision and game theory).

The moral point of view itself is often spelled out as grounded on a conception of equal respect (see Equality; Respect for persons). But there is some debate about how impartial morality requires us to be (see Impartiality).

Another set of issues concerns what it is that gives a being moral status, either as an object of moral concern or as an actual moral agent (see Moral agents; Moral standing; Responsibility). And how do our understandings of human nature impinge on our conception of morality and moral agency (see Morality and identity)?

Once we have some grip on what ethics is, we can begin to ask questions about moral principles themselves. Moral principles have often been put in terms of what is required by duty, but there has been something of a reaction against this notion (see Duty). Some have seen it as outdated, depending on a conception of divine law with little relevance to the modern world (see Anscombe, G.E.M.; Schopenhauer, A.); while others have reacted against it as a result of a masculine overemphasis on rules at the cost of empathy and care (see Feminist ethics; Wollstonecraft, M.).

These doubts are related to general concerns about the role principles should play in ethical thought. Situation ethicists suggest that circumstances can lead to the abandonment of any moral principle, particularists arguing that this is because it cannot be assumed that a reason that applies in one case will apply in others (see Moral particularism; Situation ethics). The casuistical tradition has employed moral principles, but on the understanding that there is no 'super-principle' to decide conflicts of principles (see Casuistry). At the other end of the spectrum, some philosophers have sought to understand morality as itself constituted by a single principle, such as that not to lie (see Wollaston, W.).

Duties have been seen also as constituting only a part of morality, allowing for the possibility of heroically going beyond the call of duty (see Supererogation). This is a matter of the scope of the notion of duty within morality. There are also issues concerning the scope of moral principles more generally. Does a given moral principle apply everywhere, and at all times, or is morality somehow bounded by space or time (see Moral relativism; Universalism in ethics)? This question is related to that concerning what is going on when someone allows morality to guide them, or asserts a moral principle (see Epistemology and ethics; Moral judgment; Moral knowledge). How is the capacity of moral judgment acquired (see Moral education)? The view that humans possess a special moral sense or capacity for intuition, often identified with conscience, is still found among contemporary intuitionists (see Common-sense ethics; Conscience; Cudworth, R.; Hutcheson, F.; Intuitionism in ethics; Moral sense theories; Moore, G.E.; Ross, W.D.; Shaftesbury). Scepticism about the claims of morality, however, remains a common view (see Moral scepticism; Nietzsche, F.).

In recent centuries, a dichotomy has opened up between those who believe that morality is based solely on reason, and those who suggest that some nonrational component such as desire or emotion is also involved (see Hume, D.; Morality and emotions; Rationalism). Denial of pure rationalism need not lead to the giving up of morality. Much work in the twentieth century was devoted to the question whether moral judgments were best understood as beliefs (and so candidates for truth and falsity), or as disguised expressions of emotions or commands (see Analytic ethics; Emotivism; Hare, R.M.; Logic of ethical discourse; Prescriptivism; Stevenson, C.L.). Can there be moral experts, or is each person entirely responsible for developing their own morality (see Existentialist ethics; Moral expertise)? These questions have been seen as closely tied to issues concerning moral motivation itself (see Moral motivation). Moral judgments seem to motivate people, so it is tempting to think that they crucially involve a desire.

Moral principles can be understood to rest on moral values, and debate continues about how to characterize these values and about how many evaluative assumptions are required to ground ethical claims (see Axiology; Constructivism in ethics; Moral pluralism; Values). Against the emotivists and others, moral realists have asserted the existence of values, some identifying moral properties with those properties postulated in a fully scientific worldview (see Fact/value distinction; Moral realism; Naturalism in ethics; Value, ontological status of).

2 Ethical concepts and ethical theories

Some philosophical ethics is broad and general, seeking to find general principles or explanations of morality. Much, however, focuses on analysis of notions central to ethics itself. One such notion which has been the focus of much discussion in recent years is that of autonomy (see Autonomy, ethical). The interest in self-governance sits alongside other issues concerning the self, its moral nature and its ethical relation to others (see Akrasia; Determinism and indeterminism; Evolution and ethics; Free will; Self-deception, ethics of; Self-respect; Will, the); and the relations of these selves in a social context (see Recognition; Solidarity; Vulnerability and finitude). Other topics discussed include the nature of moral ideals, and the notions of desert and moral responsibility (see Ideals; Desert and merit; Moral luck).

The question of what makes for a human life that is good for the person living it has been at the heart of ethics since the Greek philosophers enquired into *eudaimonia* (‘happiness’) (see Aristotle; Eudaimonia; Happiness; Life, meaning of; Plato; Socrates). Once again, a philosopher’s theory of the good will almost always be closely bound up with their views on other central matters (see Good, theories of the). For example, some of those who put weight on sense experience in our understanding of the world have been tempted by the view that the good consists entirely in a particular kind of experience, pleasure (see Empiricism; Pleasure). Others have claimed that there is more to life than mere pleasure, and that the good life consists in fulfilling our complex human nature (see Perfectionism; Self-realization). Nor have philosophers forgotten ‘the bad’ (see Evil; Suffering; Suffering, Buddhist views of origination of).

Moral philosophy, or ethics, has long been at least partly concerned with the advocacy of particular ways of living or acting. Some traditions have now declined (see Asceticism; MacIntyre, A.); but there is still a large range of views on how we should live. One central modern tradition is that of consequentialism (see Consequentialism). On this view, as it is usually understood, we are required by morality to bring about the greatest good overall (see Teleological ethics). The nature of any particular consequentialist view, therefore, depends on its view of the good.

The most influential theory has been that the only good is the welfare or happiness of individual human and other animals, which, when combined with consequentialism, is utilitarianism (see Bentham, J.; Mill, J.S.; Utilitarianism).

It is commonly said that consequentialist views are based on the good, rather than on the right (see Right and good; Rights). Theories based on the right may be described as deontological (see Deontological ethics). The towering figure in the deontological tradition has been the eighteenth-century German philosopher, Immanuel Kant (see Kant, I.; Kantian ethics). Such theories will claim, for example, that we should keep a promise even if more good overall would come from breaking it, or that there are restrictions on what we can intentionally do in pursuit of the good (see Double effect, principle of; Promising).

In the second half of the twentieth century there was a reaction against some of the perceived excesses of consequentialist and deontological ethics, and a return to the ancient notion of the virtues (see Aretē; Theological virtues; Virtue ethics; Virtues and vices). Work in this area has consisted partly in attacks on modern ethics, but also in further elaborations and analyses of the virtues and related concepts (see Charity; Forgiveness and mercy; Help and beneficence; Honour; Hope; Innocence; Love; Prudence; Self-control; Trust; Truthfulness).

3 Applied ethics

Philosophical ethics has always been to some degree applied to real-life. Aristotle, for example, believed that there was no point in studying ethics unless it would have some beneficial effect on the way one lived one's life. But, since the 1960s, there has been a renewed interest in detailed discussion of particular issues of contemporary practical concern (see Applied ethics).

One area in which ethics has always played an important role is medicine, in particular in issues involving life and death (see Bioethics; Bioethics, Jewish; Life and death; Medical ethics; Suicide, ethics of). Recently, partly as a result of advances in science and technology, new areas of enquiry have been explored (see Genetics and ethics; Reproduction and ethics). In addition, certain parts of medical practice which previously lacked their own distinctive ethics have begun to develop them (see Nursing ethics).

This development is part of a wider movement involving research into the ethical requirements on those with particular occupations. Some of this research is again related to scientific advance and its implications for public policy (see Information technology and ethics; Responsibilities of scientists and intellectuals; Risk; Technology and ethics). But, again, attention has also been given to occupations not in the past subjected to much philosophical ethical analysis (see Business ethics; Journalism, ethics of; Professional ethics; Sport and ethics).

The planet, and those who live and will live on it, have in recent times become the focus of much political concern, and this has had its effect on philosophy (see Agricultural ethics; Animals and ethics; Development ethics; Ecological philosophy; Environmental ethics; Future generations, obligations to; Population and ethics). But just as the scope of ethical enquiry has broadened, so there has been renewed interest in the specific details of human relationships, whether personal or between society, state and individual (see Economics and ethics; Market, ethics of the; Family, ethics and the; Friendship; Paternalism; Political philosophy; Pornography; Sexuality, philosophy of).

Ethics in Islamic philosophy

*The study of Islamic ethics, whether philosophical or theological, grew out of early discussions of the questions of predetermination (*qadar*), obligation (*taklif*) and the injustices of temporal rulers, particularly the caliphs. Early writers on ethics from the Mu'tazila school were probably influenced by Greek philosophy. By the third century AH (ninth century AD) a clearly discernible current of philosophical ethics began to take shape, with strong influences from Greek ethics including Stoicism, Platonism and Aristotelianism.*

Al-Kindi, the first genuine philosopher of Islam, appears from his extant ethical writings to have been particularly influenced by Socrates and Diogenes the Cynic. Other classical influences can be seen in the work of Platonists such as Abu Bakr al-Razi, who followed Plato's division of the parts of the souls, and Neoplatonists such as al-Farabi, while Aristotelian influences can be seen in al-Farabi, who also discussed the problem of evil, Ibn Sina and Ibn Rushd. Ibn Sina developed a theory of the conjunction of the soul with the active intellect; with this conjunction is bound up the ultimate perfection of the soul which has attained the highest degree of wisdom and virtue.

Neoplatonism again surfaces in the work of Ibn Miskawayh and his followers, to whom we owe the groundwork of a whole ethical tradition which flourished in Persia well into the twelfth century AH (eighteenth century AD) and beyond. Onto Plato's threefold division of the soul, Ibn Miskawayh grafts a threefold division of virtue into wisdom, courage and temperance. His views were elaborated upon by al-Tusi and al-Dawwani, among others. A blend of philosophical and religious ethics is characteristic of the work of some later writers such as al-Ghazali and Fakhr al-Din al-Razi, in which the road to moral and spiritual perfection has mystical overtones.

1 Theological preludes

The earliest ethical discussions in the seventh and eighth centuries appear to have centred on the question of *qadar*, which could equally mean 'capacity', as predicated of man, or 'predetermination', as predicated of God. The early so-called Qadarites of Damascus raised the question of *qadar* in the context of the moral responsibilities of the Umayyad caliphs, who justified their most oppressive policies on the ground that they were part of the divine decree (*qada' wa qadar*). Subsequently, the Mu'tazilite theologians of Basra and Baghdad refined upon the speculation of their Qadarite predecessors and attempted for the first time to give an adequate definition of right and wrong and its bearing on God's justice and his decrees in the world. This definition was expressed in essentially rationalist and deontological terms and was received with disapproval by their traditionalist and conservative rivals, who adhered to a voluntarist thesis according to which right is by definition what God commands and wrong is what he prohibits (see Ash'ariyya and Mu'tazila §5).

Other instances of Mu'tazilite rationalism include the espousal of the absolute identity of God's essence and his attributes, the irreversibility of his decrees and the freedom of the will as a precondition of moral responsibility. Mu'tazilite theologians also stressed God's wisdom and goodness and exonerated him of the responsibility for evil in the world, which was 'created' by humankind. The degree to which Mu'tazilite theological ethics was influenced by Greek philosophy cannot be fully determined from our present knowledge of the early sources, since the translation of philosophical texts had not been started by the time the founder of the school, Wasil ibn 'Ata, launched this radical theological movement in the second century AH (eighth century AD). However, contact with Christian theologians, such as John of Damascus and his disciple Theodore Abu Qurrah, was definitely a factor in initiating the Qadarite theologians, the forerunners of the Mu'tazila, into the scholastic methods of discourse that Syriac-speaking Christian scholars had been applying to theological questions prior to the Arab conquest of Syria, Egypt and Iraq.

2 The rise of philosophical ethics: early Socratic and Stoic trends

Al-Kindi, the first genuine philosopher of Islam, was also the first writer on philosophical ethics, and it is significant that he was in sympathy with Mu'tazilite theology during the heyday of that movement. However, unlike his Mu'tazilite contemporaries, whose starting-point was the Qur'an and the Traditions (*hadith*) of Muhammad, al-Kindi's starting point was Greek philosophy. He is reported by the classical bibliographers to have written a number of ethical treatises reflecting a profound interest in Socratic thought. Thus, in addition to a

treatise on *Ethics*, he is credited with a work on *Paving the Way to Virtue*, as well as an extant tract, *Fi al-hila li-daf‘ al-ahzan (On the Art of Dispelling Sorrows)*. Of his Socratic writings, a tract on the *Excellence of Socrates*, *A Dialogue between Socrates and Aschines* and a short collection, *Alfaz Sugrat (Socratic Utterances)*, which has survived, are mentioned in the classical sources.

It is noteworthy, however, that in the last-mentioned collection the personalities of Socrates and Diogenes the Cynic (see Diogenes of Sinope) are fused and both emerge as paragons of virtue and asceticism. However, in the more discursive *Fi al-hila li-daf‘ al-ahzan* the Stoic ideal of *apatheia* (freedom from passion) and the consequent indifference to the vicissitudes of fortune are set out in eloquent terms. The antidote of sorrow, which al-Kindi argues in Stoic fashion is inseparable from humanity’s ephemeral condition in this world of generation and corruption, is to consider that sorrow results either from our actions or from the actions of others. In the first case, it is our duty as rational agents to refrain from doing that which is the cause of sorrow. In the second case, averting the sorrow which results from the actions of others is either in our power or it is not. If it is in our power, we ought certainly to avert it; if it is not in our power, we should not grieve at the prospect of injury in the hope that it might somehow be turned away. However, should we nevertheless be afflicted by sorrow resulting from actions over which we have no control, it is our duty as rational beings to bear this with fortitude. This view, and the exhortation to shun material possessions as temporary acquisitions of which we are mere borrowers and not real owners, reflect clearly the influences of the great second-century Stoic teacher Epictetus and appear to derive from his famous *Enchiridion*.

However, it was Socrates and his disciple Plato who were at the centre of the moral-ascetic speculation of the early Muslim ethical philosophers. Abu Bakr al-Razi, in his ethical treatise *al-Tibb al-ruhani (The Spiritual Physic)*, refers to Plato as ‘the master of the Philosophers and their leader’, and to his teacher Socrates as ‘the ascetic and godly’ sage. He speaks of the three Platonic parts of the soul as the rational or divine, the irascible or animal and the concupiscent or vegetative souls, as these parts are designated by the Alexandrian physician-philosopher Galen in a treatise on ethics (which has survived in Arabic translation only). He then proceeds to summarize Plato’s teaching on the manner in which each of the parts or ‘souls’ should be ‘managed’ through reasoning and demonstration, a process which he labels ‘spiritual physic’ or therapy.

Another Socratic-Platonic theme which recurs in al-Razi’s writings is the folly of the hedonistic life which turns man into a slave or a beast. Because so many of our pleasures are either ephemeral or unattainable, we are assailed by anxiety or grief. But the true philosopher will not succumb to grief, because he understands that nothing in this world of generation and corruption is ever permanent and that whatever cannot be turned away should be ignored or disregarded, since it is often the product of passion and not of reason: ‘For reason summons us only to what is susceptible of bringing about profit sooner or later; grief does not bring any advantage…. That is why the perfectly rational man will only follow the summons of reason…and will never follow the summons of passion or allow himself to be led by it or get close to it’ (*Rasa’il al-Razi al-falsafiya*: 69).

Like Socrates and Plato, al-Razi believed that the soul on leaving the body will return to its original abode in the intelligible world, after passing through an endless cycle of purifications. That, he argues, is why the fear of death is irrational, and like al-Kindi and other moral philosophers he admonishes the truly reasonable man to resign himself to the prospect of death as a logical consequence of our being human. As al-Kindi had written: ‘Since the definition of man is that he is a living, dying, rational being, then if there was no death, there would be no man’ (*al-Hila li-daf‘ al-ahzan*: 45), death being an essential part of the very definition of man.

However, al-Razi adds to this argument another argument which appears to derive from Epicurus, namely that death is the privation of sensation (see Epicureanism §13); in death, man is stripped of the sensations of pleasure or pain and thus is in a better condition than the living who are constantly subjected to pain, let alone the fact that pleasure sought by our concupiscent nature is really nothing but ‘relief from pain’ or return to the natural condition (as Plato has taught in the *Philebus*). Therefore, ‘according to the judgment of reason the condition of death is better than the condition of life’ (*Rasa’il al-Razi al-falsafiya*: 93).

3 The advent of Aristotle

The first systematic writer on philosophical questions in Islam was al-Farabi, who had also contributed to ethical discussions. He is reported in the classical sources to have written a commentary on ‘parts’ of the *Nicomachean*

Ethics, translated into Arabic by Ishaq ibn Hunayn. This commentary is lost, but judging from an extant collection of *Fusul muntaza'ah (Excerpts on Ethics)*,which he is established as having written, he appears to have followed Aristotle's lead in dividing the virtues into moral (practical) and intellectual (see Aristotle §§22-25). The former, he says, are the virtues or perfections of the concupiscent part or faculty of the soul; they include temperance, courage, liberality and justice. The latter are the perfections of the intellectual part and include practical reasoning, good judgment, sagacity and sound understanding.

In his discussion of justice, al-Farabi also follows Aristotle's lead, arguing that justice consists in the equitable distribution of 'common goods' in the city or the state. These goods include security, wealth, dignity and public office, of which every member of the city or state is entitled to a share. Another more general meaning of justice is given as 'man's exercise of virtuous actions in himself and in relation to others, whatever such a virtue might be'.

An interesting feature of al-Farabi's ethics which has no Aristotelian parallel is the discussion of evil. He starts in Neoplatonic fashion by asserting that 'evil has no existence as such in anything found in these worlds; that is generally in whatever does not exist through human volition. Everything therein is good' (*Fusul muntaza'a*: 81). Evil, then, is a predicate of human action, not of physical occurrences. However, al-Farabi disagrees with traditional Neoplatonists who identified being with the good and not-being with evil pure and simple, on the ground that 'being is good only when it is in conformity with justice (or merit); not-being is evil when it is not in conformity with justice' (*Fusul muntaza'a*: 81). This appears to reflect Heraclitus' concept of *dike* as chaos (see Heraclitus §3).

Al-Farabi's successor and spiritual disciple Ibn Sina (Avicenna) is the author of a very short tract on ethics which follows closely the Platonic model in psychology. Ibn Sina divides the soul into the rational, irascible and concupiscent, to which correspond the virtues of wisdom, courage and temperance respectively, and with justice being the 'summation' of all three. To ensure the enforcement of justice within the state, argues Ibn Sina, the existence of the caliph, as conceived of by the Shi'ites, is necessary as the sovereign of the world and God's vicegerent on earth.

More explicitly than al-Farabi, Ibn Sina develops in his psychological writings a theory of conjunction (*ittisal*) of the soul with the active intellect, that supermundane agency which according to the Muslim Neoplatonists governs the sublunary world (see Neoplatonism in Islamic philosophy §2). With this conjunction, he argues, is bound up the ultimate perfection of the soul which has attained the highest degree of wisdom and virtue, becoming thereby a replica or a mirror of the higher intelligible world. Therein lies man's ultimate happiness while his soul is still in the body.

Ibn Rushd, the great Aristotelian philosopher and commentator, is known from the bibliographical sources to have written a paraphrase and a middle commentary on the *Nicomachean Ethics*, which have survived only in Hebrew and Latin, together with a paraphrase of Plato's *Republic* which is also relevant to his ethical theory. The principal virtues, according to Ibn Rushd, correspond to the perfection of the three parts of the soul, the rational, the irascible and the concupiscent. Justice is then described along Platonic lines as the 'harmony' of the three corresponding virtues of wisdom, courage and temperance; but it has, as Aristotle stated in the *Nicomachean Ethics*, two subdivisions which Ibn Rushd calls common or universal, corresponding to 'perfect virtue', and particular, whose further subdivisions are distributive and rectificatory. Contrary to expectations, however, Ibn Rushd does not identify happiness with the contemplative life, as Aristotle (§26) had done, but rather with conjunction (*ittisal*) with the active intellect, which the Muslim Neoplatonists - with whom he was at loggerheads - had regarded as man's ultimate goal.

4 Ibn Miskawayh and the Persian writers on ethics

The most important writer on ethics in Islam, however, was an eclectic who inclined to Platonism, Ahmad ibn Muhammad Ibn Miskawayh. He laid down in his *Tahdhib al-akhlaq (The Cultivation of Morals)* and other ethical writings the groundwork for a whole tradition of Persian ethical writing, the chief representatives of which were Nasir-i Khusraw (d. AH 467/AD 1074), Nasir al-Din al-Tusi, Jalal al-Din al-Dawani, Hussain Kashifi (d. AH 910/AD 1504), Mulla Ahmad Nuraqi (d. AH 1244/AD 1828) among others.

The psychological basis of Ibn Miskawayh's ethics is clearly Platonic, as was generally the case in Islamic philosophical circles. Onto Plato's threefold division of the soul (see Plato §14), as modified by Galen, he grafts a

threefold division of virtue into wisdom, corresponding to the rational part of the soul; courage, corresponding to the irascible part; and temperance, corresponding to the concupiscent part. Justice, which Ibn Miskawayh describes as a form of moderation (*i'tidal*) or proportion (*nisba*), arises when the three powers or parts of the soul are in harmony. This virtue is not part of virtue, but virtue entire, as Aristotle (§22) had argued. Its subdivisions, according to Aristotle as interpreted probably by Porphyry, are then given as three: our duties to God, to our superiors or equals, and finally to our ancestors. Ibn Miskawayh, however, refers to the genuine Aristotelian twofold subdivisions of justice into distributive and rectificatory and predicates the exercise of this supreme virtue on submission to the holy law (*shari'a*), which emanates from God. He then assigns to the 'just imam' or caliph the function of warding off the different forms of violating justice. Ibn Miskawayh even attributes to Aristotle, quoting an apocryphal Aristotelian source in Arabic translation, the view that justice stipulates rendering God the kind of worship due to him as our beneficent creator.

However, the Neoplatonic element in Ibn Miskawayh's ethics is nowhere more pronounced than in his analysis of happiness. Its two subdivisions, according to him, are practical and theoretical. The latter consists in 'conjunction' with the active intellect, whereby man is able to join the 'higher intellectual' realm. However, Ibn Miskawayh recognizes beyond this intellectual perfection a 'divine' or supernatural condition whereby man partakes of divine perfection or achieves a condition of self-divinization which goes far beyond his worldly conditions. This 'divine condition' is also alleged to derive from an Aristotelian fragment *On the Virtues of the Soul*, which Ibn Miskawayh quotes in Arabic translation, but which is clearly different from the apocryphal tract of the Aristotelian corpus known as *De virtutibus et vitiis*.

Ibn Miskawayh's two best-known Persian followers are Nasir al-Din al-Tusi, author of *Akhlaq-i Nasiri (Nasirean Ethics)*, and Jalal al-Din al-Dawani, author of *Lawami al-ishraq fi makarim al-akhlaq (Flashes of Illumination on the Nobility of Character)*, known also as *Akhlaq-i Jalali*. Both al-Tusi and al-Dawani follow closely the lead of Ibn Miskawayh in the *Tahdhib al-akhlaq*. A fundamental difference between Ibn Miskawayh and the latter two authors is the addition of 'household management' and politics to the purely ethical part of their work by both al-Tusi and al-Dawwani. This may be viewed as a broadening, in Aristotelian fashion, of the scope of practical philosophy, which Ibn Miskawayh had tended to confine to ethical discourse only.

In the political section, inspired chiefly by al-Farabi, al-Tusi argues that orderly association is an essential precondition of the good life. Of the three forms of government, the monarchical, the tyrannical and the democratic (which he attributes to Aristotle), he favours the monarchical, identified like Plato's with the 'rule of the virtuous' or aristocrats. However, the true monarch is assisted by divine inspiration but is subordinate to the imam, who according to Shi'ite doctrine is in 'temporary concealment'. This monarch acts accordingly in a vicarious or interim capacity to ensure the administration of justice in the absence of the true head of the community or 'hidden imam'.

Al-Dawani's ethical treatise follows essentially al-Tusi's lead, but in genuine Shi'ite fashion he stresses more than his predecessor the position of humans as God's vicegerent (*khalifa*) on earth (Surah 2: 30). In mystical fashion, he then goes on to argue that people reflect in their capacity as God's vicegerent the dual character of the divine nature, the outer and the inner, the spiritual and the corporeal, and more than any other creatures, including the angels, can be described as the 'image' of God. The foremost duty of the ruler, he argues, is to preserve the ordinances of the divine law (*shari'a*) and to conduct the affairs of state in accordance with universal principles and the requirements of the times. The ruler is for that reason God's 'shadow' and the vicar of the Prophet.

5 Philosophical and religious ethics

A specific blend of philosophical and religious ethics is characteristic of the writings of some late authors, including al-Raghib al-Isfahani (d. AH 502/AD 1108), Abu Hamid al-Ghazali, Fakhr al-Din al-Razi and others. Al-Ghazali is the foremost representative of this group, who in both his ethical treatise *Mizan al-amal (The Balance of Action)* and his religious summa, *al-Ihya' 'ulum al-din (The Revival of the Religious Sciences)*, has developed an ethical theory in which Platonic psychology serves as the groundwork of an essentially Islamic and mystical worldview. In this theory, the table of the four cardinal virtues accords with the Platonic virtues but admits of a series of subdivisions or ramifications analogous to those of his predecessors. A good example of the combination of religious and philosophical ideas in al-Ghazali is the manner in which happiness can be achieved. Happiness, as the chief good, admits of two subdivisions, the worldly and the otherworldly. Otherworldly

happiness, which is our ultimate goal, cannot be achieved without certain worldly goods. These include the four cardinal virtues of wisdom, courage, temperance and justice, the bodily virtues of health, strength, good fortune and a long life, the external virtues of wealth, kin, social position and noble birth, and finally the 'divine virtues' of guidance, good counsel, direction and divine support. Those virtues are referred to in the Qur'an and the *hadith*, al-Ghazali says, and the final virtue, 'divine support', is identified with the Holy Spirit (Surah 2: 87, 253) (see Virtues and vices).

The road to moral and spiritual perfection is described as the 'quest for God'. The seekers after God must satisfy two conditions: their actions must be governed by the prescriptions or ordinances of the 'divine law' (*al-shar'*), and they must ensure that God is constantly present in their hearts. By this presence al-Ghazali means genuine contrition, adoration and submission, born of the seeker's awareness of the beauty and majesty of God which al-Ghazali, like other Muslim mystics or Sufis, regards as analogous to human passion or love (*'ishq*) (see Mystical philosophy in Islam).

Ethiopia, philosophy in

Ethiopia is a unique phenomenon in Africa for three reasons. First, because of its historical continuity and political independence; second because of its written language and third because of its written philosophy. Ethiopian philosophy in the broadest sense is expressed in both oral and written language. In this entry only the written documents are dealt with. This methodological approach limits the investigation to linguistic and cultural phenomena as it deals with the ancient Semitic language known as Ethiopic and the Christian zones of influence on the high plateaus of Ethiopia.

There are five basic texts of Ethiopian philosophical literature: the Physiologue (the Fisalgwos) (c. *fifth century* AD*), The Book of the Wise Philosophers (1510/22), The Life and Maxims of Skendes* (c. *eleventh century* AD*), The Treatise of Zar'a Ya'ecob (1667) and The Treatise of Wäldä Heywåt* (c. *eighteenth century). The first three are adaptations of works transmitted from Greek sources through Arabic; the latter two (appearing in modern publications in a combined form) are original works of a rationalist flavour.*

1 The basic texts

The Ethiopic *Physiologue* (*c*. fifth century AD), a naturalistic-theological book of Christian symbolism, is a translation and adaptation from the Greek original. The Greek *Physiologue* seems to have been written between the end of the second century AD and the beginning of the third. There is near unanimity among scholars that Alexandria, Egypt was the place where it was revised. The Ethiopian translation was probably adapted around the beginning or middle of the fifth century. It was completed in Egypt by an Ethiopian living in a monastery of Skete where he had access to the Greek original.

The sixteenth century is particularly rich in the history of Ethiopic literature with a philosophical slant. At this time, Abba Mikael, an Egyptian, translated and adapted into Ethiopic *The Book of the Wise Philosophers* (1510/22). After its adaptation, an Ethiopian transcribed it into on parchment in Ethiopic. The Arabic text is thought to have been written by Hunain ibn Ishâq (*c*.809-?), the son of a Nestorian Christian. The Arabic version is based on the lost Greek original. This original belonged to the later literature of apophthegm in the form in which it flourished during the Byzantine period (seventh to early ninth century). The Greek influence is evident throughout *The Book of the Wise Philosophers* in its allusion to Presocratic (sixth and fifth centuries BC), Socratic (469-399 BC), Aristotelian (384-322 BC), and especially Platonic (427-347 BC) and Neoplatonic (from third to sixth or seventh centuries AD) dialogues. *The Book of the Wise Philosophers* is a collection of sayings, or a *liber sententiarum*. It presents the quintessence of what various philosophers have said on a certain number of topics, the greater number of which are ethical.

The Life and Maxims of Skendes (*c*. eleventh century AD) was also translated and adapted from the Arabic into Ethiopic at this time, although the identity of the author is unknown. The Arabic story seems to have been based on a Greek original of the second century AD. A careful examination of the Ethiopic and the Arabic texts shows that the Ethiopian translator of this version of the Oedipus story is clearly a deeply thinking person with sensitive powers of perception. The Skendes story, as it is conveyed in Ethiopic, is the most perfect and morally chastened of all preserved accounts of this type.

A close comparison of the Arabic, Ethiopic and Greek texts (there are parallels of the lost Greek original in other Greek works) reveals that the Ethiopians never translate literally except for the Holy Scriptures. They adapt, modify, add and subtract. A translation therefore bears a typically Ethiopian stamp. Although the nucleus of what is translated is foreign, the way it is assimilated and transformed is typically Ethiopian. This phenomenon, which is not limited to philosophical works but also applies to other cultural areas like iconography, is known as 'creative incorporation'.

The Treatise of Zar'a Ya'ecob (1667) is original in many ways. The author begins the treatise with the story of his life. It is the only autobiography in Ethiopic literature. Zar'a Ya'ecob (1599-1692) was born in the environs of Aksum, northwest Ethiopia. He attended traditional Ethiopian schools and attained the highest learning levels. Afterwards he taught Holy Scriptures for ten years. Denounced before the king, he was compelled to flee for his life. On his way to Shoa in the south (Addis Ababa is the modern capital of the province of Shoa), he found an

uninhabited cave at the foot of a valley, where he lived for two years. In peace and solitude he developed his philosophy. His philosophy is presented as the fruit of his own personal reflection and not as a translation-adaptation from foreign sources as is the case with most Ethiopic literature. It is clearly rationalistic in a religious (not scientific) sense. Rationalism is understood as the view which recognizes as true only that content of faith which can be made to appeal to reason. In Ethiopia, traditional philosophy in its written form is closely linked with Christianity in general and monasticism in particular. Zar'a Ya'ecob's rationalism, in contrast, insists precisely on the absolute and exclusive sufficiency of human reason and denies all dogmatic assertion that reason is unable to establish by its own means.

Through the application of his method, the light of reason, whose immediacy enlightened his investigation, Zar'a Ya'ecob discovered a basic principle: the goodness of created nature. From this foundation he moved towards theodicy, ethics and psychology. In his ethics, because he accepted the fundamental goodness of creation, he endorsed married life and the enjoyment of food, and rejected the time-honoured traditions of celibacy and fasting in Ethiopian monastic life. In his psychology he emphasized the freedom of the human and their superiority over the rest of creation.

As a contemporary of René Descartes, Zar'a Ya'ecob resembled him in many ways, although Ya'ecob did not make use of the method of universal doubt. In both these philosophers one finds a method, occasion for a critical inquiry and the discovery of a criterion that leads to the establishment of a basic principle, which is then applied in both authors to theodicy, ethics and psychology. Also in both, the method of inquiry is revolutionary, although its roots are deeply theological. The historical circumstances from which the rationalism of both philosophers originated are equally similar. They are based in the collapse of scholasticism, the harmony between faith and reason in Europe, and in Ethiopia, the confrontation with Western culture and violent religious discord (see Descartes, R. §1).

Zar'a Ya'ecob, unlike Descartes, was not a mathematical genius. His philosophy does not develop deductively as a linear growth from a first principle or original idea, but rather, like the unfolding of the sun's rays, it emanates from a single centre and safeguards the complexity and richness of reality.

After his death, Zar'a Ya'ecob's disciple Wäldä Heywåt wrote *The Treatise of Wäldä Heywåt* (*c*. eighteenth century) in which his master's last years are related and his thought is presented in a more pedagogical and accessible fashion.

2 From wisdom to rationalism

The five basic texts that have been presented span more than twelve centuries of literary production. They show a double evolution: from translation, the *Physiologue* (*c*. fifth century AD), with its frequent misunderstandings, *The Book of the Wise Philosophers* (1510/22), with its intuitions, *The Life and Maxims of Skendes* (*c*. eleventh century AD), with its sensitive, reflective perceptions) to originality, *The Treatise of Zar'a Ya'ecob* (1667), *The Treatise of Wäldä Heywåt* (*c*. eighteenth century); from wisdom to rationalism. The link with Christianity evolves from the Christian symbolism of the *Physiologue* to the theologically-oriented anthropocentrism of *The Book of the Wise Philosophers*, to the theistic pantheism of the first series of maxims in *The Life and Maxims of Skendes* to the anti-Christian, though mystical radicalism of Zar'a Ya'ecob and his disciple.

However, it is the very notion of philosophy, in both a broad and narrow sense, which shows the greatest evolution. In the widest sense it is synonymous with wisdom understood as involving knowledge and the ability, inclination and steady purpose of putting knowledge to good use. Thus evidence of wisdom in a person involves an end or purpose to be attained, an understanding of this purpose and an effort to achieve it in the best possible manner. Objectively, wisdom is the sum total of things worth knowing and ends worth working for.

The Book of the Wise Philosophers and *The Life and Maxims of Skendes* attempt, each in their own way, to express wisdom in the broad sense of philosophy. *The Book of the Wise Philosophers* presents the simplest and most common form of wisdom literature: the *angarä*, or saying. *The Life and Maxims of Skendes*, on the other hand, is a philosophical novel. The second and third sections, within the question and answer frame, cover the spectrum of forms of wisdom literature, including maxims, numbers, exhortations and the biographical portrait.

The Treatise of Zar'a Ya'ecob and *The Treatise of Wäldä Heywåt* are philosophy in a stricter sense. Each is the

result of the reflection of one person, and each has a clearly defined method, characterized by criticism, inquiry (the name of the treatise in Ethiopic is *hatätä*, or inquiry), and the use of the criterion of the light of reason as a basis upon which the whole edifice is founded. But, within the same rationalistic approach, a clear distinction appears between the master and his disciple. Zar'a Ya'ecob is the only one of the two who presents in a complete, systematic and original way, the methodology of his philosophy. Although Wäldä Heywåt shares the ideas of his master, the starting point and the dialectical movement from this origin are not found in his treatise. In this sense, he is in line with Ethiopian traditional thought (see Rationalism).

Since the *Physiologue* is not a philosophical work, one may ask why it has been placed at the beginning of a series of texts on Ethiopian philosophical literature. The following quotation might indicate why:

> Seen from the vantage point of later developments in Ethiopian philosophy, especially the XVI, XVII and XVIII centuries, the Fisalgʷos (the Physiologue) affords a first glimpse into its rudimentary beginning. It is like observing a great river in its initial streamlets. Nearly all the main characteristics of Ethiopian philosophy that will flourish in Mäshafä fälasfa (The Book of the Wise Philosophers), The Life and Maxims of Skendes, and The Treatise of Zar'a Ya'ecob and of Wäldä Heywåt are already present in the Fisalgʷos, although in an inchoate way: its thought patterns, its archetypal images and symbolism, its world view…, its anthropology, its social approach and its set of ethical values. Without the later developments of Ethiopian philosophy, the Fisalgʷos is deprived of its significance; without the Fisalgʷos, Ethiopian philosophy is deprived of its roots.
>
> (Sumner 1985: 8-9)

3 Dialectical pattern

Like ancient and medieval philosophies in Europe, classical Ethiopian philosophical literature has a definite beginning and end. The history of Ethiopian philosophy appears as a dialectical process representing a curve rather than a straight line. This curve is also apparent within *The Life and Maxims of Skendes*, as it moves from the life of Skendes through the first series of maxims and into the second.

The thesis of the dialectical pattern is represented by Ethiopian philosophy of Greek origin. Just as Aristotelian thought was introduced into the Latin medieval world through translations made from the original Greek into Arabic and later into Latin, Greek Platonic and Aristotelian thought was introduced into Ethiopia during the sixteenth century by translations made from the original Greek into Arabic and later into Ethiopic. This stage can be seen in *The Book of the Wise Philosophers* and *The Life and Maxims of Skendes*. The Ethiopian response to this alien influence did not represent a slavish adherence to imported forms, but rather, a creative incorporation. These two works offer adaptations which are so free and original that they are practically the equivalent of an authentic Ethiopian work. The link with Christianity is also apparent in both works.

Zar'a Ya'ecob's work breaks the intimate link with Christianity in general and monasticism in particular, even though his thought remains profoundly theistic. Therefore, he represents an antithetic position to the works of his predecessors. The departure is even greater if one considers that his work is original, the product of personal reflection and not a translation or adaptation from foreign sources.

The treatise written by Wäldä Heywåt after his master's death attempted to synthesize Ya'ecob's ideas with the traditional wisdom literature represented by *The Book of the Wise Philosophers*. His treatise is interspersed with illustrations taken from this sixteenth-century work, although they are more dramatic and picturesque in Wäldä Heywåt than in their original models. The result of this synthesis is no less deep than his master's investigation, but does establish a rapport between the autobiographical insights of Ya'ecob and other practical and educational considerations.

Wäldä Heywåt represents a major contribution to Ethiopian philosophy with respect to ordinary human life. His treatise stresses the value of work, develops a social philosophy with its different practical applications, affirms the equality of all human beings whatever their beliefs, and insists on the beauty of marriage and family life. Yet looked at from the perspective of originality, critical rigour and methodological structure, the synthesis represented by Wäldä Heywåt's treatise is not the summit of the dialectical movement. The line that began with wisdom literature and ascended in an original arc curves back on itself.

Ethnophilosophy, African

Ethnophilosophy refers to bodies of belief and knowledge that have philosophical relevance and which can be redescribed in terms drawn from academic philosophy, but which have not been consciously formulated as philosophy by philosophers. These bodies of belief and knowledge are manifested in the thoughts and actions of people who share a common culture.

Most of the literature on ethnophilosophy is written about African cultures. Ethnophilosophy's most immediate African antecedents include Leopold Senghor's philosophy of négritude *and the writings of the Belgian missionary to the Congo (later Zaire), Placide Tempels. Ethnophilosophy examines the systems of thought of existing and precolonial African communities in order to determine what can be the ideal forms of 'authentic' African philosophy and praxis in the emerging postcolonial situation. In addition to the pioneering work of Senghor and Tempels, this school is represented in the writings of philosopher Alexis Kagamé (1956) and theologian John Mbiti (1969) among others, many of whom were regarded as Tempels's disciples.*

The central themes of the work of these disciples include assertions that there is a unified 'Bantu philosophy' and that its fundamental categories are manifested in features of language such as grammar, or features of culture such as cosmology and ritual. According to many of these authors writing about Bantu philosophy, the boundaries between self and other are not as rigid as in Western philosophy. Also, interdependence rather than competition is a primary social value and the human and nonhuman world is animated by a 'vital force', which underlies the perception of reality.

1 Defining ethnophilosophy

The literature defining African socialism can be included in the ethnophilosophical approach. This is a body of materials combining Marxist social and economic theories with *négritude*'s politics of difference. Two works by Nyerere ((1968a, 1968b) reveal that these political accounts share with other works of ethnophilosophy the thesis that the central values of Africa are communal rather than individual (see Ethical systems, African). The definition of ethnophilosophy is complex and ambiguous because it arises out of a basic ambiguity in the definition of philosophy itself. The idea of philosophy refers to two related but separable orders of discourse. The first order is located in the forms of talk and action found among the ordinary members of society and elaborated by them in the course of their everyday life and activities. In common parlance, a person, group, historical period or culture could be referred to as having a philosophy when the systematic nature of their moral judgments, the ontological notions that underlie their view of the world, the ways in which they argue and the criteria of evidence and truth that are exhibited in their arguments are under discussion. Usually the philosophy attributed to a person or social entity is not consciously held or espoused, but is part of the tacit set of conventions that make discourse intelligible.

The second order of discourse is dependent on the first order and uses first-order discourse to develop a self-consciously critical order of discourse that is philosophical in a narrower sense and is perceived as having the capacity to correct the flaws of first-order discourse. This is the critical aspect of second-order discourse, but it can also have a speculative side that has not always been acknowledged by the analytic movement which has dominated so much of the history of modern philosophy.

The second problem in defining philosophy as second-order discourse returns to the basic question of defining ethnophilosophy. In a sense all philosophy is culturally shaped and socially determined. It is doubtful that any form of discourse is independent of its cultural and social contexts. If that is so, then all thought, even second-order thought, is shaped by such aspects of the lives of thinkers as their identity, social relations and the culture they share in common with their audiences and interlocutors. From a sociological and anthropological point of view all philosophy is ethnophilosophy. The distinction between first- and second-order thinking, while useful as a means of distinguishing modes of thought used within a single setting, does not help a great deal in specifying the defining features of philosophy believed to transcend the cultural and historical contexts in which they were elaborated.

These observations suggest a second definition for ethnophilosophy which arises more from the practices of philosophers than from the definitions they themselves have offered: ethnophilosophy is a term used to describe

the bodies of belief and knowledge defined by colonized people whose institutions cannot easily be assimilated into models derived from the Western experience in general and the Enlightenment in particular, notably those historical contexts out of which the modern discipline of (Western) philosophy emerged and from which it draws its specificity. From this point of view the ambiguity that created ethnophilosophy has little to do with the people to whom the term is applied and much to do with the social contexts from which a specialism such as philosophy is derived.

2 African ethnophilosophy

Both African socialism and more strictly philosophical works of ethnophilosophy celebrate the subordination of the individual to the community that they argue is central to African culture and philosophy. On the surface this position appears to be radically non-Western and opposed to the emphasis on the adversarial individual in Western thought and culture. Actually it accepts a distinct opposition between individual and community that is not only Western but profoundly rooted in nineteenth-century utilitarian thought. The primary difference between utilitarian thinkers and ethnophilosophers on the subject of the individual and community is that the direction of causation is reversed. In the philosophy of the social sciences, for example, the utilitarian position known as ‘methodological individualism’ asserts that collective and communal forms are reducible to calculating individuals. In ethnophilosophy, by contrast, individuals are reducible to (or explicable in terms of) communities (see Holism and individualism in history and social science).

A number of contradictions are exhibited in ethnophilosophical writings. First and foremost, they remain profoundly descriptive and nonjudgmental, that is noncritical, about African traditions and customs. But they are generally offered in the service of a discourse that is powerfully critical of colonial rule and culture. This is the basis for the reproach aimed at ethnophilosophy by the African philosophers Paulin Hontoundji (1983) and Kwasi Wiredu 1980), that critical discourse cannot exempt one side from the criticism it levels at the other side.

What is even more important, however, is the criticism that ethnophilosophy is oppositional without being radical. On the surface ethnophilosophy is robustly anti-colonial, yet it still accepts the basic categories in terms of which colonial culture defines other cultures and peoples. It attempts to re-evaluate them instead of seeking to criticize the grounds out of which colonial discourse emerges, such as the distinction between culture and civilization, or the primitive or ‘traditional’ and the ‘modern’.

Thus, it appears that ethnophilosophy has two contradictory aspects. It is a critical discourse that defines itself in opposition to colonialism, yet it begins by accepting the colonial categories of traditional and modern. The most significant difference between the original colonial categories and their use in ethnophilosophy is that instead of treating them as diametrically opposed in the colonial fashion, ethnophilosophy tries to merge them by re-appraising indigenous values as worthy of attention and then accordingly discovering the traditional in the modern.

Ethnophilosophers tend to be scholars trained in the West who work on materials derived from outside the cultural contexts in which they were trained. The context and structure of their work engages them in an activity that is culturally hybridized. Since many of them are Africans, the hybridity also works in the other direction, from Africa to the West. Ethnophilosophers have occasionally used the hybrid nature of their cultural productions to create knowledge that is itself hybrid by arguing that characteristics of Western intellectual history can be found in African traditional thought. For example Alexis Kagamé((1956) argues that African thought utilizes Aristotelian and Thomistic elements. Placide Tempels(1959), arguably the father of ethnohistory, even founded a Catholic religious movement in the Congo (later Zaire) based on the convergence of Bantu philosophy and Christianity.

The literature on ethnophilosophy does not usually combine discussions of ethnophilosophy proper with accounts of the writings on African socialism and Afrocentricity. The notable exception is Anthony Appiah’s *In My Father’s House* (1982) which examines nationalist themes and assertions about the person found in pan-Africanism, the counterhegemonic discourses on race and the literature on African philosophy (see Pan-Africanism). Appiah’s work represents a rare attempt to take a stance which acknowledges the ways in which philosophical discourse emerges from cultural and historical conditions and is manifested in a range of materials that include but are not limited to philosophy. By avoiding the increasingly sterile debate about whether African discourse has a second-order dimension, Appiah is able to discuss philosophical aspects of a broad range of

materials in a way that has escaped the grasp of philosophers more concerned with the boundaries of their discipline.

Perhaps the most notable characteristic of the ethnophilosophy school was its characterization of philosophy as a kind of collective narrative. Ethnophilosophers treated African philosophy as a narrative whose content is revealed through various codes, such as myth, symbolic systems and religious and ordinary language. In this sense, although African philosophy was represented as an innate form of indigenous expression, it could only be recovered and re-evaluated from a hybridized postcolonial present. This is another example of ethnophilosophers' ambivalent mediation between two points, the 'traditional' and the 'modern'.

3 Ethnophilosophy and the politics of culture

The political implications of ethnophilosophy are also displayed in the idea that traditional knowledge is or was collectively produced and appropriated. This central theme of ethnophilosophy suggests that individuals cannot be free; that in a society where knowledge is a collective product, cultural criticism is not possible. This in turn raises fundamental questions about personhood, agency and the possibility of change.

The idea that African thought is collective and unchanging has been accepted by some of the critics of ethnophilosophy. Hountondji 1983) and Wiredu (1980) argue that the capacity for change depends on three elements of Western Enlightenment inheritance lacking in traditional societies: individual freedom, abstract theory and openness to alternative theories and interpretation. In their view traditional philosophy appears to reject these features of thought. Wiredu (1980) identifies these with science and sees hope for this redemption in the application of analytic practice as people seek new methods and solutions to old problems. Hountondji (1983) proposes that this redemption takes as its foundation Althusserian neo-Marxist notions which he believes govern the mobility of knowledge through history. Both regard the individual as the agent of change through social and cultural criticism. In other words, Wiredu and Hountondji defend the colonial and postcolonial as the new spatial and temporal realities not to be ignored by Africa.

This countercritique ranks the West above the traditional as they separate the past from the present. This is because the influence of the past on the present should be minimized to avoid anachronism. In effect, it offers an alternative representation of the hybrid postcolonial social and cultural condition.

The critique of ethnophilosophy began around the 1960s after the first works of ethnophilosophy were published. Among the first critics of ethnophilosophy was Franz Crahay (1965). In his paper 'Le Décollage Conceptuel: Conditions d'une Philosophie bantoue' (Conceptual Launch: the Terms of a Bantu Philosophy) he argued that the colonial distinction between the traditional and the modern is analogous to the distinction between 'constructing myth' and 'practising philosophy'. This distinction is in turn similar to the metaphysical distinction between form and matter. Although form and matter make complementary contributions to the identity of things, they none the less remain conceptually distinct in nature and function. According to this perspective philosophy like form is of the mind. It deals with those elements of thought in which experience as event and practice is presented in and to our minds. It deals with ideas, related to and distinct from the particulars from which they derive. Though it is a human practice, philosophy diverges from other human practices such as customary ways of living and traditional (or any) group behavioural patterns.

Like matter, myth, tradition, custom and mores are glued to the sensual mode of experience. Their language remains unabstracted from the metaphors and experiences of everyday life; they are sociologically immediate and concrete. In this sense Crahay (1965) argues that while philosophy frees itself from its conceptually limiting fixation with sociological conditions by 'taking-off' to a free, or universal conceptual level, ethnophilosophy remains trapped in the closed confines of sociological structures and relativism like anthropology. In anthropology the argument that African systems of thought have been closed was developed by Robin Horton (1967). He argues that the nature of African social structures prevents African thought treating society and nature as abstract rather than personalized. In his view social relations are the idiom for thinking about natural elements, not vice versa.

The difficulty with the critics of ethnophilosophy, as well as with the alternatives developed by scholars such as Horton, is that by reserving criticism for themselves, the authors of this literature also reserve the role of criticism for the Western trained philosopher. This position implicitly supposes that traditional African society is still collective and so cannot regenerate itself by means of social and cultural criticism. From a political point of view

the strategy of constructing a subject who can only be represented by an other is characteristic of nationalist thought and assertion, where some political actor or writer sets themselves up as the voice and representative of an emerging collectivity which can not speak for itself. The parallel between ethnophilosophy and nationalist discourse is not accidental. The guiding assumption of ethnophilosophy, that philosophical notions can be held unconsciously, requires a conscious agent to represent and lead the mass of ordinary Africans to a different world and a better life. This political project shared by ethnophilosophy and many of its critics is unmistakably nationalist and modernist. It is organized by ideas about progress and divides the social world into two classes, citizens who are critically self-aware agents and subjects who have yet to acquire the cultural apparatus that would enable them to become citizens. The debate about whether Africans and others possess second-order modes of thought also exhibits modernist premises about critical self-awareness, but is more concerned with the relationship of philosophy (as an emergent profession) with society than with how cultures should be classified. Ethnophilosophy brings together two usually separate cultural arenas: professional discourse and cultural discourse. The result sheds light on unresolved issues in the definition of philosophy, as well as problems of how cultures are classified and ranked.

Eudaimonia

The literal sense of the Greek word eudaimonia *is 'having a good guardian spirit': that is, the state of having an objectively desirable life, universally agreed by ancient philosophical theory and popular thought to be the supreme human good. This objective character distinguishes it from the modern concept of happiness: a subjectively satisfactory life. Much ancient theory concerns the question of what constitutes the good life: for example, whether virtue is sufficient for it, as Socrates and the Stoics held, or whether external goods are also necessary, as Aristotle maintained. Immoralists such as Thrasymachus (in Plato's* Republic*) sought to discredit morality by arguing that it prevents the achievement of* eudaimonia, *while its defenders (including Plato) argued that it is necessary and/or sufficient for* eudaimonia. *The primacy of* eudaimonia *does not, however, imply either egoism (since altruism may itself be a constituent of the good life), or consequentialism (since the good life need not be specifiable independently of the moral life). The gulf between 'eudaimonistic' and 'Kantian' theories is therefore narrower than is generally thought.*

1 Conventional morality and Aristotle

The word *eudaimonia* and the corresponding adjective *eudaimōn* are derived from *eu* 'good, well' and *daimōn* 'spirit', giving the literal sense 'having a good guardian spirit', hence being blessed, having the life of one who enjoys divine favour. To possess *eudaimonia* is to have a life which is objectively desirable, and thereby to have achieved the most worthwhile of conditions available to humans. It thus overlaps substantially with the modern concept of happiness (see Happiness), where that is conceived, not as a (possibly short-lived) episode of feeling, but as a condition characterizing a whole life, or a substantial part of it, as when one wishes a newly married couple happiness in their life together. But even when thus conceived, happiness in the modern sense is determined primarily by one's subjective attitude to one's life; broadly, to be happy is to be content with one's life, whereas contentment with one's life, although arguably necessary for *eudaimonia*, is not sufficient for it. According to Aristotle (§21) (*Nicomachean Ethics*, 1095a15-22) everyone agrees (1) that *eudaimonia* is the highest human good and (2) that the word means 'doing and living well', but there are substantive disagreements on what kind of life counts as doing and living well. Some kinds, such as the life devoted to bodily pleasure, are disqualified not on the ground that people who live like that are always dissatisfied, but because they fail to satisfy objective requirements for a worthwhile life, in particular that it should be an excellent realization of specifically human potentiality. Again, Aristotle asserts (1100a1-2) that a child is not *eudaimōn*, meaning not that no one has a happy childhood, but that the life of a child is not one in which human potential is realized to its highest bent.

In popular usage the term has strong connotations of material prosperity, traditionally regarded as one of the signal marks of divine favour. This conception is in tension with a more specifically ethical one, according to which the condition of the agent's personality or character is at least the primary determinant of living well. The latter conception, found already in Democritus §§15-16 (fr. 171), finds its strongest expression in the Socratic thesis, later adopted as the cardinal tenet of Stoicism, that virtue is the only intrinsic human good and wickedness the only intrinsic evil (see Stoicism §15-16). Aristotle's treatment (*Nicomachean Ethics* I 7-10) is a characteristic exercise in reconciliation of these standpoints. On the one hand *eudaimonia* must be comprehensive and self-sufficient, requirements which seem to imply that it includes the gifts of fortune; on the other the achievement of the good life must be in our power. Aristotle's middle way is the thesis that excellence or virtue (see Aretē) of character and intellect is (1) indispensable for the good life, (2) although not totally invulnerable, less subject to the vicissitudes of fortune than anything else. Hence the achievement of excellence, although not strictly sufficient for *eudaimonia*, as Socrates arguably and the Stoics certainly claimed, comes as close to guaranteeing it as the limitations of human life permit.

2 Attacks on conventional morality

Since *eudaimonia* was universally agreed to be the good, critics of conventional morality such as Antiphon, Callicles (in Plato's *Gorgias*) and Thrasymachus (in Plato's *Republic*) sought to devalue morality by arguing that it hinders or prevents the achievement of *eudaimonia*, while defenders of morality sought to show that it is necessary and/or sufficient for *eudaimonia*. The attacks assume that *eudaimonia* is to be achieved through the gratification of desire, whereas morality requires resistance to or suppression of desire; the defences take different

forms. One line of defence, seen in Democritus, Protagoras' myth (in Plato's *Protagoras*) and Glaucon's social contract account of morality in *Republic* II, stresses the benefits which the individual derives from social institutions, for the existence of which morality is necessary. In the *Republic* (see Plato §14) Plato takes the more radical step of internalizing social morality; the 'individual' is in fact a community in miniature, and the requirements of morality are therefore reduced to the proper organization of that community: that is, to the harmonious organization of the 'individual' personality. Plato, and Greek philosophers generally, take the primacy of individual *eudaimonia* pretty well for granted; the possibility that morality might require the sacrifice of the agent's *eudaimonia* for the good of others, or of society, is hardly canvassed.

This raises the difficult problem of the extent to which Greek ethical theory allowed for altruism. Certainly, all the main writers and schools - Plato, Aristotle, Epicurus and the Stoics - stress the importance of one form or another of social life, whether that of the city, the Epicurean community or the cosmos as a whole, insisting that interpersonal ties of one or other kind are themselves essential constituents of individual *eudaimonia* (see Aristotle §§27-8; Epicureanism §11; Stoicism §14). If the most worthwhile life is the most excellent one, and the most excellent thing to do is to sacrifice one's life for one's friend, as Aristotle recommends, or to take one's turn ruling instead of devoting oneself full-time to metaphysics, as Plato requires of his guardians in the *Republic*, then in sacrificing oneself one does not sacrifice, but perfects, one's *eudaimonia*. The primacy of *eudaimonia* is thus preserved, but at the cost of moralizing the concept of *eudaimonia* itself; the good life includes the moral (whether the just or the altruistic) life as an essential component. This in turn threatens the project of defending morality by showing it to be necessary and/or sufficient for the independently acknowledged good of *eudaimonia*.

3 Eudaimonistic and Kantian ethics

The primacy of *eudaimonia* in Greek ethical thought standardly leads to its being characterized as 'teleological', in opposition to 'deontological' theories of a Kantian type (see Teleological ethics; Deontological ethics), in which the fundamental concept is that of obligation binding on all rational beings (see Kant §9). This contrast is superficial. As we have seen, 'eudaimonistic' theories need not be consequentialist, since the good life need not be specifiable independently of the moral life (see Consequentialism). Furthermore, the tendency of much Greek thought, notably that of Plato, Aristotle and the Stoics, to identify the real self with the rational self tends towards the identification of the achievement of *eudaimonia* with conformity to demands of reason. The Stoic community of all rational nature is the forerunner of the Kantian kingdom of ends.

Eudoxus (*c*.390-*c*.340 BC)

Eudoxus of Cnidos was a Greek mathematician with wide-ranging philosophical and scientific interests. He was known in antiquity for his mathematical astronomy and his philosophical hedonism, and placed, if loosely, within the Pythagorean tradition. More recently, debate about the correspondence between mathematical models produced by astronomers and the physical motions of the astronomical bodies themselves has focused especially on Eudoxus, since he is generally regarded as the first to have used a mathematical model in astronomy.

Very little about Eudoxus' life and work is known with any certainty. Diogenes Laertius (VIII 86-91), in his biography of Eudoxus, reports that he was called 'Endoxus' ('illustrious') because of his brilliant reputation. None of his works survives, only accounts and fragments in other ancient authors. Even the long-standing belief that he was a leading member of Plato's Academy (see Academy) is now in doubt. However, there is evidence that he founded a school at Cyzicus, on the Hellespont, which may have survived into the third century BC. Tantalizingly little is known about his relationships to such important contemporaries as his supposed teacher Archytas, Plato and Aristotle. Anecdotes relate his invention of a type of sundial, and his introduction of the practice of arranging furniture in a semi-circle to accommodate more people.

Eudoxus is mentioned, together with Anaxagoras, by Aristotle in his arguments against the theory of Platonic Forms (see Aristotle §15). The reference is short and ambiguous; consequently scholars have debated whether Eudoxus actually had a 'theory' of Forms. Alexander of Aphrodisias, in his commentary on Aristotle, provides a lengthier discussion of what he understands as Eudoxus' views, including the idea that forms are mixed together with and are 'homoeomerous' (of like parts) to those things they inform. Eudoxus can be understood as suggesting that forms are immanent (rather than transcendent), for they are physical ingredients in entities (Dancy 1991).

Eudoxus is particularly celebrated for his geometric model of planetary motion. According to the ancient story, he was the first to answer Plato's challenge to account for the apparently irregular motions of the celestial bodies by using only uniform, circular and regular motions in order to describe the phenomena or 'save the appearances'. He devised a separate system of nested homocentric spheres to describe the apparent motions of each of the heavenly bodies (reported by Aristotle in *Metaphysics* XII 8). Writing much later, Simplicius explained that according to Eudoxus the path of a planet describes a figure called a 'hippopede' or horse-fetter. Eudoxus was able to account for various phenomena and 'save the appearances' in an approximate way, although not all phenomena could be explained, including the changing brightness of planets. Aristotle mentions that Callipus (of Cyzicus) adopted Eudoxus' approach but added to the number of spheres, in order to explain the phenomena better. Aristotle objected to the number of spheres of both Eudoxus and Callipus, and offered his own improvements to the system. Although the ancient descriptions of Eudoxus' astronomy are brief, several nineteenth century scholars reconstructed in detail the geometry thought to underlie his solution.

Questions regarding the application of mathematical methods to the explanation of natural phenomena are of great interest to historians and philosophers of science, and Eudoxus' work often figures importantly in their discussions. Eudoxus played a key role in the history of science, according to Pierre Duhem, who was himself a proponent of an instrumentalist view of science and, as a physicist, philosopher and historian of science, was interested in the relationship between mathematics and physics (Duhem 1908) (see Scientific realism and antirealism §1; Ptolemy). According to instrumentalists, theories permit predictions which correspond to observations, but do not necessarily describe physical reality. Many, including Duhem, have assumed that Eudoxus did not believe that his geometric model had any physical reality. This would qualify Eudoxus as the first 'instrumentalist' in the history of science. However, the paucity of our knowledge of Eudoxus' work makes any statement regarding the intention underlying his astronomical solution purely speculative.

Within the broader context of early Greek astronomy, it has been suggested that Eudoxus' originality lay in providing the basis of a geometric explanation useful in accounts of problems of practical interest, namely the risings and settings of stars, in geographical studies, and in justifying a more mathematically sophisticated sundial (Goldstein and Bowen 1983). On this view, Eudoxus' work represents a synthesis of two existing activities, calendar-making and cosmological theorizing, and his introduction of a geometric model to explain celestial motions inaugurated a new phase in astronomy.

It is tempting to look for some connection between Eudoxus' astronomical work and his ethical philosophy. Both the science of music and cosmological speculation may have had an important influence on him: the Pythagoreans and Plato were already pointing to a moral order manifested in the circular motions of the heavenly bodies (see Pythagoreanism §§2-3). Furthermore, there is evidence that theological concerns motivated the followers of Eudoxus in his school at Cyzicus (Sedley 1976).

As a hedonist, Eudoxus thought that pleasure was the good and the goal of life (see Hedonism). Aristotle (*Nicomachean Ethics* X 2) explains Eudoxus' argument, which was based on the observation that all things aim towards pleasure. Because that which is the object of choice is excellent and that which is most the object of choice is most excellent, the fact that all things move towards the same goal indicates that for all things it is the good. Aristotle observes that Eudoxus' views regarding pleasure were taken seriously because of his good character, rather than on their own merits. Because he was regarded as remarkably self-controlled, it was thought that Eudoxus presented his views 'not simply as a friend of pleasure, but because the facts really were so'.

Eurasian movement

The Eurasian movement was a creation of émigré Russian intellectuals following the First World War and the October Revolution. The ideology of Eurasianism was formally proclaimed in 1921. It obtained considerable development, prominence, distinction and notoriety in the two following decades, essentially running its course by the time of the Second World War. Eurasianism attracts attention because of the novelty and originality of its central argument, proposing that the Russian Empire and later the Soviet Union constituted an independent organic entity separate from both Europe and Asia, called Eurasia (it was the complete separation from Europe that represented an explosive novelty), and because of the intellectual variety and abilities, at times brilliance, of its proponents. Also, as an extraordinary phenomenon in Russian intellectual history, it demands explanation.

1 Eurasianism

Eurasianism emerged quite explicitly in 1921 when four young Russian intellectuals published a collective volume, *Iskhod k vostoku (Exodus to the East)*. The four were Prince Nikolai Sergeevich Trubetskoi (1890-1938), later to earn fame as a linguistic scholar, Pëtr Nikolaevich Savitskii (1894-1968), an economist-geographer and specialist in many subjects, Pëtr Petrovich Suvchinskii (1892-1985), a gifted music critic and many-sided intellectual, and Georgii Vasilievich Florovskii (1893-1979), a theologian, intellectual historian, and a man of numerous interests with a remarkable breadth of knowledge. The anthology consisted of an introduction and ten essays.

The introduction spoke of a world cataclysm, of a catastrophic change of scenes, of a new age, of the dying of the West and of the imminent rise of the East. It concluded: ‘Russians and those who belong to the peoples of "the Russian world" are neither Europeans nor Asiatics. Merging with the native element of culture and life which surrounds us, we are not ashamed to declare ourselves *Eurasians*’ (1921: 7).

In the essays which followed Florovskii and Suvchinskii concentrated on a fundamental and sweeping criticism of the hopelessly rationalistic, war-devastated, and moribund West, as well as on the catastrophe of Russian history and society, which eventuated in the unparalleled disaster of communist revolution; Savitskii and Trubetskoi, however, paid major attention to the new redeeming concept of Eurasia. In an essay on ’The Migration of Culture’ Savitskii outlined how in world history cultural centres and leadership moved with each millennium to colder and colder climates; if the migration continued, the next step will transfer the world leadership to Canada and ’northern Minnesota’ on the one hand, and on the other to ’parts of northern and central Russia together with all of eastern Russia, both eastern European Russia and Siberia’. And in another essay, ’Continent-Ocean (Russia and the World Market)’, the economist and geographer insisted that because of its landlocked position and huge bulk Russia had to minimize recourse to oceanic trade routes and devote itself instead to the entirely feasible rich and varied development of its own continental economy. Trubetskoi’s essay, ’The Upper and Lower Layers of Russian Culture (The Ethnic Base of Russian Culture)’, sketched in effect cultural Eurasia: in contrast to the superficially and unsuccessfully Westernized upper classes, Russian masses and their culture were in no sense simply European, because proto-Slav dialects (and hence the Russian language) occupied a middle geographic position between the proto-Indo-Iranian and proto-Western-Indo-European ones, closer to the former than to the latter in essential characteristics; because Great Russian folk songs utilized the ’five-tone’ or ’Indo-Chinese’ scale; because Russian folk dance, in contrast to Western dance, was not based on a couple, a man and a woman, dancing together; because Russian material culture indicated the closest possible association with Ugrofinnic peoples; because Russians had Ugrofinnic and Turkic as well as Slav blood; because they were inclined to oriental contemplation and devotion to ritual, but also to *udal’*, extravagant daring or audacity, ’a purely steppe virtue, which the Turkic peoples understand, but neither the Romanogermans nor the Slavs can’, and so on. The two Eurasias, Savitskii’s geopolitical and Trubetskoi’s cultural, became partners but also independent streams in the new ideology.

The first Eurasian symposium was followed by others, the seventh and last coming out in 1931. Also, twelve volumes of the *Evraziiskaia khronika (Eurasian Chronicle)* appeared between 1925 and 1937, and they were joined by numerous individual publications by participants in the movement. Indeed in the 1920s and 1930s Eurasianism acquired some prominence and attracted much attention among Russian exiles in Europe. Eurasian

publications were supplemented by ’seminars’, public lectures, formal debates and private disputations. Although Florovskii, one of the founders, rather quickly abandoned Eurasianism and in 1928 published a crushing critique of it, other émigré intellectuals, a few of them of great prominence, joined the movement. Thus Roman Osipovich Jakobson (1896-1982), another linguist of the first rank, followed Trubetskoi’s lead to make some remarkable discoveries about languages in Eurasia, while Georgii Vladimirovich Vernadsky (1887-1973) became the prolific Eurasian historian, and, because he taught Russian history at Yale and published many books in English, the greatest propagandist of Eurasianism to the world outside Russian émigré circles. The movement also displayed a certain political bent, even aspiring to replace communism, regarded as a rival and undesirable ideocracy, in the government of Russia-Eurasia. Still, always confined to a small minority and essentially to one particular generation of exiles, the Eurasian movement ended with the new perturbations of the Second World War and the decline and death of the generation in question.

2 The historical position of Eurasianism

Eurasianism is both easy and difficult to understand and explain. It certainly belongs with other European doctrines of bitterness, suffering and despair, as well as at times apocalyptic hopes, which proliferated after the First World War and the disasters which attended and followed it. In the Russian case the October Revolution, civil war and famine could be considered even more horrible than the great War itself, and they all found rich response in Eurasianism. Still another major historical development, described by phrases like the rise of colonial peoples, the decline of imperialism, or the gradual loss by the so-called White race of its dominant global position, also found powerful response. In fact, Trubetskoi had published already in 1920, the year preceding the inauguration of Eurasianism, a brief book *Europe and Mankind*, which was a relentless indictment of imperialism and a declaration of essential Russian solidarity with colonial peoples.

The difficulty resides in the positive part of the Eurasian teaching, in the concept of Eurasia itself. More exactly, of the two main versions of that concept, Savitskii’s geopolitical Eurasia found considerable understanding and some approval. But Trubetskoi’s cultural Eurasia, the alleged Eurasian identity of the Russians, exploded among the émigrés like a bombshell. No Russian intellectual prior to the Eurasian movement had denied a fundamental Russian affiliation with Europe. Such severe critics of the West as the Slavophiles and Dostoevskii emphasized the very point that the West was guilty of not treating Russians like brothers. Nikolai Danilevskii, it is true, rejected the West, but his entire allegiance went to Slavdom and the coming Slav age in Europe (see Pan-Slavism §3). The new identity was so revolutionary and so baffling that most critics totally failed to understand, let alone accept it. Where did this identity come from? A few disparate suggestions appear possible. As already indicated, the Eurasians reacted to the new phenomenon of the rise of the colonial peoples. Moreover, without doubting the sincerity of Eurasians, it seems clear that if Eurasia, organic and glorious, were also real, the Russian or the Soviet Empire, rebaptized Eurasia, would have perdured in the age when other empires crumbled. The Russian intellectual climate also made its contributions. Russian scholarship was in the process of discovering ever more about the character and the role of non-Slav peoples, whether Finnic tribes of the north or steppe inhabitants to the southeast, in Russian history and culture. Beyond that, on the eve of the appearance of Eurasianism a few poets, most notably Aleksandr Blok in a poem entitled ’The Scythians’ written 30 January 1918, began to identify the Russians themselves as such an intermediate people between Europe and Asia. Finally, the personal circumstances of the Eurasians deserve consideration. They were gifted young intellectuals ready to participate in the cultural leadership of Russia, when Russia disappeared (and they found themselves permanently in exile). Eurasianism can be regarded as a desperate bid to compensate for that loss.

Essentially fantastic and certainly abortive, Eurasianism deserves attention because of its intellectual variety and richness and also as a sign of the times. Understandably it has attracted new interest with the collapse of the Soviet Union and the Russian search for identity.

Eusebius (*c.* AD 264-*c.*339)

Eusebius, Bishop of Caesarea in Palestine from c.*314, was the foremost Christian scholar of his age and wrote extensively on history, geography, chronology, apologetics and philosophical and biblical theology. He is best known for his pioneering History of the Church, but philosophers may prefer to consult his Preparation of the Gospel, which argues that basic Christian doctrines had been foreshadowed by well-known philosophers and preserves valuable extracts from writers whose works have otherwise been lost. In his own philosophical ideas, Eusebius was strongly influenced by classical philosophy, especially Platonism, and sought to reconcile this with Christian theology.*

1 Life, works and philosophical sources

Eusebius was born *c.* AD 264 and became Bishop of Caesarea in Palestine *c.*314. The library at Caesarea contained books brought from Alexandria by Origen with additions by Eusebius' mentor Pamphilus. Eusebius became an enormously industrious and wide-ranging scholar with a good general knowledge of philosophy. His *Historia ecclesiastica* (History of the Church) appeared in successive editions from *c.*300 onwards. His *Praeparatio evangelica* (Preparation of the Gospel), in fifteen books, was written *c.*312-18; it argues that Christian doctrines were foreshadowed by the philosophers, and is an invaluable source-book, especially for Middle Platonist authors whose works have otherwise been lost. A companion work, the *Demonstratio evangelica* (Proof of the Gospel) appeared about the same time.

Eusebius was a conservative theologian, anxious to maintain clear distinctions between the three divine Persons. He had some sympathy with Arius, signed the Creed of Nicaea (325) with reluctance, and led a partially successful reaction against its extreme adherents. Yet he warmly approved of the Emperor's reforms and wrote an eloquent address in praise of Constantine (*Laus Constantini*). He died *c.*339.

Eusebius quotes Plato very freely from original texts; but his knowledge of the Presocratics and of Aristotle, Epicurus and the Stoics is plainly derivative. He uses Philo of Alexandria and Plutarch, including some works not otherwise preserved, and is an important source for Atticus and Numenius. He quotes two books of Plotinus, now known as *Enneads* IV 7 and V 1, but not from Porphyry's edition. He uses Porphyry's *Philosophy from Oracles* and other writings, despite Porphyry's anti-Christian stance, but ignores his logical works.

2 Logic and ethics

Eusebius accepts the conventional division of philosophy into ethics, physics and logic (see Stoicism §2). But his treatment of logic is perfunctory; he ignores Plato's dialectic and does not use Albinus/Alcinous or Clement of Alexandria's *Stromateis* VIII, let alone Aristotle's or Chrysippus' logic. The 'logical skill' that he claims for Hebrew writers is identified with 'comprehension of the truth itself', which he finds in the Book of Proverbs; he also argues that Hebrew names correspond with realities, appealing to Genesis 2: 19 and adducing Plato's *Cratylus*.

His treatment of ethics, again, hardly goes beyond discussion of the *summum bonum*. He adopts the conventional criticisms of Epicurus as making pleasure the sole good, and of Aristotle as teaching a 'triad of goods' which values health and prosperity as much as virtue. He does, however, cite Plato's *Philebus* 67a, which assigns a positive though limited value to pleasure. Stoic ethics pass almost unnoticed. Eusebius praises Plato for locating the good in the intelligible world and assimilates Hebrew piety to Platonism, describing God as the source of all good things, so that the 'God-loving' person alone lives a happy and blessed life. Eusebius does not discuss the Jewish law in detail, though his own moral axioms are shown indirectly in his repeated condemnation of polytheism.

3 The physical world

For Eusebius, physics includes the study of the intelligible, incorporeal world as well as perceptible things, a Platonic doctrine which he claims the Hebrews accepted. Plato agreed with Moses in regarding the world as created; and Eusebius repeatedly criticizes the doctrines of the 'physicists' - some of them were atheists, while others deified the material elements, or at least regarded matter as the ultimate reality. Anaxagoras revered a divine

creative mind, but failed to explain its operations. Parmenides, however, rightly believed in unchanging reality, and Heraclitus in a divine *logos*. Aristotle's doctrine of the eternity of the cosmos is rejected in favour of the literalist interpretation of the *Timaeus* offered by Atticus; Eusebius ignores the common Platonist view that the myth of a divine creative act really signifies eternal dependence. Epicurus rejects any providential order, and his doctrine of atoms denies the unity of the cosmos, though Eusebius apparently ignores his view that the cosmos originated in an uncaused 'swerve' of free-falling atoms. The Stoics are blamed for explaining the universe in material terms, though their concept of God as 'intelligent fire' is defended, following Clement of Alexandria, as compatible with Scripture.

Apart from accepting Empedocles' doctrine of four elements, Eusebius says little about astronomy, geography and physics in its modern sense; he is content to reproduce a doxography from Pseudo-Plutarch. His claim of a biblical 'physiology' relies on Solomon's reputed expertise (1 Kings 4: 29-34), and is not further pursued.

4 The world of Ideas, and theology

Eusebius agrees with the 'dogmatic' Platonists in the importance he attaches to the Ideas, or intelligible reality; but like most Platonists before Plotinus he fails to include them in a consistent theory. He shows no serious interest in Plato's attempts to classify the Ideas by genera and species. He presents them as eternal and unchanging and adopts the prevalent view of them as thoughts in God's mind which function as prototypes for God's works in creation. But this view is presented mainly in relation to the species of things in the world, whereas a more consistent Platonist would begin the creative process with the highest genera: possibly the Idea of mutable being, or that of the living creature as such. Eusebius takes from Philo of Alexandria and Clement a Stoicized theory which gives first place to the cosmos and its elements. Yet he also presents the Ideas as intelligent beings, which so far from being changeless are capable of 'fall and divergence' from their original position as archangels, thus becoming demons. Eusebius quotes Plato's *Laws* in support; but an assimilation of Ideas to souls, based perhaps on *Phaedo* 79 and *Sophist* 248e-249a, was assumed by Philo and many Platonists. Eusebius of course accepts the immortality of the soul, and approves Plato's description of a judgment after death, but shows without difficulty that Plato offers inconsistent pictures of the soul's continued existence.

Eusebius also draws on Platonism for his description of God's being, presenting him not only as transcending the universe but also as incomprehensible. He claims that God is 'above all intelligence and beyond every concept and consideration', which recalls the Platonic phrase 'beyond mind and being' (*epekeina nou kai ousias*), based on Plato's *Republic* 509b (compare Aristotle fr. 46). He uses the human mind and its utterance (*logos*) as an analogy for God's being and self-disclosure, but (unlike Numenius) he seldom actually designates God as mind. He thinks of the divine Logos as a distinct personality, though in a later work he notes the unpopularity of the phrase 'a second God'. Opposing any theology which blurred the distinction between the divine Persons or envisaged their unity in material terms, he gave qualified support to the strongly subordinationist view of Arius; he accepted the Creed of Nicaea (325) only with reservations.

5 Providence and human freedom

Besides creation, Eusebius upheld the doctrine of divine providence against Epicurus and others, but was also concerned to establish the freedom of the human will, as presupposed by the concepts of moral effort and of praise and blame. He therefore attacked the determinism presupposed by the astrologers and pagan oracles, and condemned as inadequate the Stoics' attempt to reconcile determinism with moral freedom. In Eusebius' view, Chrysippus offered us a 'semi-slavery'. Eusebius appealed to our consciousness of freedom and correctly pointed out that future events are differently determined. Some events are bound to happen; others result unpredictably from a coincidence of natural causes. Nevertheless, the human will is a true cause, determining some events that would otherwise be undetermined or otherwise determined, and is not itself necessarily controlled either by physical causes or by social pressures. God's providence disposes the general laws of the universe, but also cooperates with our free wills to encourage us to virtue. Eusebius presents evil in terms of human wrongdoing, no doubt presupposing the Stoic doctrine that natural disasters are not evils unless feared or resented.

All this is intelligently argued; but Eusebius does not eliminate the problems presented by the predictive element in *Christian* prophecy and by the well-established doctrine of God's total foreknowledge. Nevertheless, his philosophical ability deserved more recognition than it received. The relatively open-minded approach that he

inherited from Origen rapidly became unpopular in the Eastern Church. The Nicene Creed became the standard of orthodoxy, and Eusebius' coolness towards it was remembered; he was never canonized, and his reputation rested upon his much valued and repeatedly imitated *History of the Church*.

Evans, Gareth (1946-80)

Frege's notion of sense is a conception of content whose application is controlled by the idea of rationality. A Fregean outlook is often taken to imply that singular reference is always mediated by descriptions, and hence to be inconsistent with the insights that have motivated proponents of 'direct reference'. But in his major work, The Varieties of Reference (1982), Gareth Evans showed how a treatment of singular reference on Fregean lines can accommodate those insights. This means that the semantics of singular reference need not be distanced from the philosophy of mind, in the way that proponents of 'direct reference' typically suppose. Within the framework provided by this synthesis, Evans gave detailed treatments of the different ways in which thought and speech are directed at particular objects. Particularly notable are his discussions of demonstrative thinking, which exploits the perceptible presence to the thinker of the object it concerns; of first-personal thinking; and of singular statements of nonexistence.

1 Life

Gareth Evans was a Fellow of University College, Oxford; in 1979 he became Wilde Reader in Mental Philosophy at the University of Oxford. His articles, on issues in metaphysics, philosophy of language and philosophy of mind, are assembled in his *Collected Papers* (1985), but his major contribution to philosophy is the posthumously published *The Varieties of Reference* (1982).

2 Historical background

In the Theory of Descriptions, Russell gave a precise account of one way in which the content of an episode of thinking or speaking can be targeted on an individual, in the sense that its truth-value depends on how things are in respect of that individual: the individual is singled out by uniquely fitting a specification that figures in the content - say, 'presently reigning over France' (see Russell, B. §9; Descriptions §§2-3). It is central to Russell's point that contents of this shape are available to be entertained in an episode of thinking, whether or not anything conforms to the specification. If nothing does, the thought is simply false, not deprived of content.

Russell contrasts this kind of content with contents that are more intimately related to objects on whose properties their truth depends. A content of this second kind can be entertained only by a thinker 'acquainted with' the objects concerned, and the very existence of such a content depends on the existence of these objects. Contents of this second kind are expressed by forms of words containing what Russell calls 'logically proper names'. Compared with the first kind of content, contents of this second kind seem to be genuinely singular; and compared with definite descriptions, 'logically proper names' seem to be genuinely referring expressions.

However, Russell thinks there are hardly any 'logically proper names'. In his view one cannot entertain or express one of these genuinely singular contents if there is so much as a possibility, by the lights of hyperbolical Cartesian doubt, that one's conviction that a suitable object exists is an illusion. Thus almost all expressions that would ordinarily be classified as referring expressions (for instance ordinary proper names) must be interpreted as 'disguised descriptions' - that is, abbreviations for expressions of the specifications that figure in the other kind of content. This 'disguised description' picture became something of an orthodoxy, supposedly with referring as its subject matter, even though in Russell's own thinking the idea of referring seems more at home in connection with 'logically proper names', which Russell himself sets in contrast with 'disguised descriptions'.

Frege had argued that singular terms must be credited with senses as well as referents (see Frege, G. §3; Sense and reference §1). The sense of a sentence is the thought expressible by it, and it is the sense rather than the referent of a singular term that contributes to determining the sense of a sentence in which the term figures. Frege's point here is to delineate a notion of content, thinkable or expressible, whose employment is controlled by the idea of rationality, in a way that can be illustrated as follows. Suppose two singular terms have the same referent; take a pair of sentences which are alike except that one contains one of those terms, where the other contains the other. If a rational subject can understand these sentences and take rationally opposed attitudes to them (for instance, endorsing one and rejecting the other), then the thoughts they express must differ; and this difference in the senses of the sentences can only trace back to a difference in the senses of the singular terms.

In the orthodoxy, the Fregean idea that singular terms have senses became assimilated to the neo-Russellian idea

that they are 'disguised descriptions'; the assimilation set up a supposedly unified doctrine, against which Saul Kripke and others recoiled. Their alternative yields a liberalized analogue to Russell's conception of 'logically proper names'. In the new picture, various contextual relations between thinkers or speakers and objects play something like the role in which Russell cast 'acquaintance', and genuinely referring expressions are not as rare as Russell thought. With Frege assimilated into the orthodoxy, this new picture is conceived as rejecting the Fregean apparatus. If Fregean sense figures at all in the new picture, it is not as an aspect of the semantics of singular terms, but in a supposedly separate role, as an instrument for describing the configurations of thinkers' minds (see Proper names §1).

3 Evans on Fregean sense

Evans offers a reading of Frege that undermines this assimilation. There are three main claims. First, the assimilation is not required by the motivation for Frege's notion of sense. In the case of what singular terms contribute to thoughts, Frege's point is that if attributing propositional attitudes is to be controlled by the idea of rationality, then individuating the contents of the attitudes by the identity of the objects that figure in them is too coarse-grained. Evans insists that singular thoughts can be individuated more finely, as Frege required, but still be 'Russellian' - that is, depend for their very existence on the existence of the objects they are about.

Second, Frege himself evidently feels the attraction of such a conception. He maintains that a putative singular utterance with no referents for its putative singular terms has no truth-value. We can best make sense of that as an implication of the idea that there is no thought (of the appropriate kind) for such an utterance to express - since the thoughts that singular utterances express, when they do express thoughts, are 'Russellian'. Frege's own principles make it difficult, perhaps impossible, to make sense of the alternative idea that such an utterance does express a thought, but one with no truth-value.

Third, although Frege often seems to say that a singular term's possession of a sense does not depend on whether it has a referent, this can be explained away. Such claims belong in the context of Frege's thesis that in cases of reference-failure one lapses into fiction. In fiction, he says, one expresses apparent thoughts. This suggests that when he says that an apparent singular term can have a sense even though it lacks a referent, what he really means is that such a term gives the appearance of having a sense, not that it genuinely has a sense.

It is not as important to settle what Frege himself held as to see that his basic principles allow for expressions whose semantics - possession of senses and all - qualify them to count, by quasi-Russellian lights, as genuine singular terms, rather than something on the lines of the 'disguised descriptions' that Russell contrasts with them. This means that a broadly Fregean conception of thought and its expression can accommodate the insights of the recoil from the 'disguised description' picture. We can acknowledge cases in which reference is not mediated by descriptions, but partly constituted by contextual relations between thinkers and objects, without needing to separate such reference from the characteristically Fregean topic, the rationally organized configurations of thinkers' minds.

4 Varieties of reference

Evans gives a general account of how 'informational' relations between thinkers and objects can enter into determining referential relations between thoughts and objects, even while the thoughts are conceived in a fundamentally Fregean way, as individuated by their positions in a space of possibilities open to a rational subject. He recommends his picture by contrasting it with 'the Photograph Model of mental representation', according to which relations of 'informational' type suffice for a mental state or episode to be about an object, without any need for a Fregean framework. In a transition from philosophy of mind to philosophy of language, he discusses at a general level how 'information-based' thoughts figure in the understanding that is required for some communication.

The general picture of 'information-based' thoughts is applied in detailed accounts of thoughts of three interdependent kinds: (1) thoughts in which objects are singled out demonstratively in a way that exploits their perceptible presence to the thinker; (2) thoughts about places or regions of space expressible by the use of words such as 'here'; and (3) first-personal thoughts. A central aim is to reconcile the fact that these thoughts single out their objects egocentrically with the claim that they are targeted on elements in the objective order. The capacities

to think these thoughts belong to a subject who is experientially and practically placed in the objective world. Such a subject enjoys a course of experience understood as jointly determined by the way things are anyway and by the subject's trajectory through objective reality, and thereby knows what it is for egocentric identifications of objects (including places) to be directed at items that are also identifiable in more objective ways (for instance by map references). Evans thus displays first-personal thoughts, in particular, as being in their own way about particular objects (the human beings - animals of a certain distinctive kind - who self-consciously think them). This stands in radical contrast to the Cartesian position, in which at least some such thoughts involve reference to immaterial entities problematically related to certain animals: it also defuses a temptation to avoid the Cartesian position by denying that those thoughts involve reference to anything at all.

Evans' general account of 'informational' relations might lead one to expect discussions of thoughts linked to their objects by relations of testimony and memory, corresponding to his treatment of perceptually demonstrative thoughts. The book contains nothing answering to the former, however, and where one might expect the latter, a treatment of thoughts whose objects are singled out by the thinker's ability to recognize them. This is insightful about recognitional capacities, but arguably not well integrated into the overall structure of the book.

A problem for 'Russellian' conceptions of reference is posed by negative existential statements that appear to have singular terms in subject position (for example, 'The planet Vulcan does not exist'). The 'disguised description' picture has no difficulty here; such a statement simply says that the associated specification is not satisfied. Metalinguistic treatments are not satisfying; such a statement seems somehow to use, rather than talk about, the singular terms it contains. One would like to say: 'Such a statement says, of some specified thing (for example, the planet Vulcan), that it does not exist.' But that would describe the statement in a way that undermines what it tries to say. Evans gives an ingenious and original account of such statements, which allows us to get as close as possible to that desideratum without falling into nonsense. One can go through the motions of referring within the scope of a game of make-believe (as when one 'talks about' fictional characters); the idea is that a statement such as 'Vulcan does not exist' exploits such a game of make-believe for the serious purpose of declaring that that is all it is. The book concludes with a suggestive discussion of proper names, centring on different degrees of involvement in name-using practices.

JOHN McDOWELL

List of works

Evans, G. (1982) *The Varieties of Reference*, ed. J. McDowell, Oxford: Clarendon Press. (Evans' major work; it places Frege and Russell with respect to more recent reflection about singular reference, and discusses the various ways in which thought and speech are targeted on particular objects. Rough in places, and occasionally technical, but well worth the effort.)

Evans, G. (1985) *Collected Papers*, Oxford: Clarendon Press.(Evans' shorter writings, ranging from technical philosophy of language to general metaphysics and philosophy of mind. Perhaps especially noteworthy is the brilliant paper 'Things without the Mind'.)

References and further reading

Frege, G. (1892) 'On Sense and Meaning', in *Collected Papers on Mathematics, Logic and Philosophy*, ed. B. McGuinness, Oxford: Blackwell, 1984.(Frege's introduction of the notion of sense. A classic.)

Kripke, S. (1980) *Naming and Necessity*, Oxford: Blackwell.(A brilliant and trenchant attack on the 'disguised description' picture of how proper names refer.)

McDowell, J. (1986) 'Singular Thought and the Extent of Inner Space', in P. Pettit and J. McDowell (eds) *Subject, Thought and Context*, Oxford: Clarendon Press, 137-68. (Discusses the significance, for philosophy of mind and metaphysics, of the way Evans synthesizes a basically Fregean outlook with rejecting the 'disguised description' picture.)

Russell, B. (1905) 'On Denoting', in *Logic and Knowledge*, ed. R.C. Marsh, London: Allen & Unwin, 1956, 39-56.(Another classic: Russell's announcement of the Theory of Descriptions. Not difficult, apart from a famously opaque section on Frege.)

Russell, B. (1918) 'The Philosophy of Logical Atomism', in *Logic and Knowledge*, ed. R.C. Marsh, London: Allen & Unwin, 1956, 177-281.(Lectures for nonspecialists: contains a lucid exposition of Russell's central

doctrines about reference.)

Events

Events are entities like collisions and speeches, as opposed to things like planets and people. Many are changes, for example things being first hot and then cold. All lack a thing's full identity over time: either they are instantaneous, or they have temporal parts, like a speech's words, which stop them being wholly present at an instant; whereas things, which lack temporal parts, are wholly present throughout their lives.

Events may be identified with two types of entity: facts, like the fact that David Hume dies, corresponding to truths like 'Hume dies'; or particulars which, like things, correspond to names, for example 'Hume's death'. Which one they are taken to be affects the content of many metaphysical theories: such as that all particulars are things; that times, or causes and effects, or actions, are events; or that mental events are physical.

1 Events and things

Many kinds of entity, from any cause or effect to everything a space-time region contains, have been called 'events'. But events usually so-called - deaths, collisions, speeches - form an apparently distinct kind, different from things like people, planets and books (see Continuants). What is the difference? Many events are changes, for example, human bodies being first alive and then dead. But this may not define events. For first, we may need events to distinguish intrinsic changes, like dying, from some relational ones, like being orphaned; the latter being mere entailments of the former, which are real events, with contiguous causes and effects (see Change). Second, events that begin or end things, like the Big Bang and other explosions, cannot be changes in them and may not, if nothing precedes or survives them, be changes in anything else.

The difference between things and events, whether changes or not, may be that things keep a full identity over time, which events lack. First, some events may be instantaneous and lack any identity over time. Second, temporally extended events are deprived of full identity over time by their temporal parts, like a speech's spoken words, which stop them ever being wholly present at an instant; whereas people and other things have no temporal parts and are wholly present at every instant of their lives. This full identity over time will then distinguish one thing changing from successive things having different properties, thus explaining why only things can change and why changes, being events, are not things (Mellor 1981).

This difference may be denied by giving things temporal parts by definition, such as Hume-in-1739. But these are mere logical constructions from things and times, not independent events like the words in a speech. Some apparent things might indeed be mere strings of contiguous and causally related events (it has been suggested, for example, that we are strings of experiences). But not all: unchanging elementary particles involve no independent events. Moreover, since contiguity and causation can always link one event or thing to two successors, as when a cell divides, they cannot entail a thing's identity over time (see Personal identity). So, equating us to strings of experiences implies not that things can be strings of events but that we are not things. Events and things remain distinct types of entity.

2 Events and facts

Assuming there are things, are there also events? That may depend on whether events are facts, corresponding to truths like 'Hume dies in 1776', or particulars corresponding to names or descriptions like 'Hume's death' (see Facts; Particulars). Changes look like facts, for example the fact that a thing is first hot and then cold; and that things start and cease to exist at certain times are also facts. Thus events of both types mentioned above may be facts, and what many authors call 'events' certainly are: Kim (1976), for whom events are things having properties at times, like Hume being alive in 1775, is an example. Events in this sense are real entities if and only if facts are.

This being so, 'event' is best reserved, as by Davidson, for particulars like Hume's death. Their reality is independent of that of facts, but equally contentious: after all, the only particular apparently referred to in 'Hume dies' is Hume. Yet Davidson argues that 'Hume dies' also entails that an event exists which is a death of Hume. For first, this shows how 'Hume dies slowly' entails 'Hume dies', since a slow death must be a death. Second, identifying actions with particular events satisfying different descriptions dissolves puzzles about their identity: for example my bid can be a purchase even though many bids are not purchases (see Action). Similarly, if mental

events are particulars, they can also be physical brain events satisfying neurophysiological descriptions (see Identity theory of mind). This explains, without invoking non-physical causes or effects, how events satisfying mental descriptions - such as ‘is a decision to bid’ - can have physical causes and effects, like hand movements (see Anomalous monism). This explanation assumes moreover that causes and effects are particulars, not facts, and this requires particular events. For only if Hume’s death exists can the effect of whatever caused Hume to die be a particular; otherwise the effect can only be the fact that Hume dies.

All these arguments have been disputed. Events remain more contentious than things, despite having identity criteria: for example, that a headache is a certain brain event if it has the same causes and effects as that event. Yet since such criteria may only relate particular events to each other, we may still need people and other things to identify some events to start with, as in ‘Hume’s death’ (see Strawson, P.F.). This may explain scepticism about events, but cannot make them less real than things, or less able to be particulars. For to be a particular is just to be of a kind we make true first-order generalizations about (see Quine, W.V.), many of which, like Newton’s ‘to every action there is always opposed an equal reaction’, are about events as well as things.

Evil

Evil is serious unjustified harm inflicted on sentient beings. Two types of evil can be distinguished: 'natural evil', which is the product of nonhuman agency, and 'moral evil', which is the product of human agency. Moral thinking tends to focus on moral evil, and three main interpretations of it have been made. One, initiated by Socrates, holds moral evil to be deviation from the good; another, favoured by Stoic-Spinozists, views it as illusory; the third, made originally by Leibniz, sees it as a contrast necessary for the existence of the good. A realistic account must face the fact that moral evil does exist, and much of it is due to common human vices, which coexist with virtues in human character. It is primarily the proportion of the mixture, not the knowledge and intentions of agents, that determines how much evil will be caused by specific individuals in specific contexts.

1 The nature of evil

Evil is the most severe condemnation our moral vocabulary allows. Murder, torture, enslavement and prolonged humiliation are some examples of it. Evil must involve harm, and it must be serious enough to damage its victims' capacity to function normally (see Suffering). Furthermore, the harm must be unjustified, since not even serious harm is in itself necessarily evil, as it may be just punishment for crimes committed or the only means of preventing even greater harm (see Crime and punishment §2). What harm is justified is one of the fundamental questions of moral philosophy. The competing answers to it, however, share the key idea of a moral equilibrium. In general terms, harms that tend to maintain the moral equilibrium are justified, while those that tend to produce a disequilibrium are unjustified. The generality of this explanation allows for disagreements about what count specifically as harms, and about how the moral equilibrium can be best maintained.

Evil may be the product of human or nonhuman agency. Inclement weather that causes crop failure and widespread starvation is an example of the latter, and it is usually described as natural evil. Evil caused by human beings, such as torturing an innocent person, is moral. This traditional distinction between natural and moral evil is useful, but it should not be drawn too sharply because human beings may be natural agents, as carriers of a disease, for instance, and evil caused by natural agency may warrant moral opprobrium, if it was preventable and those responsible for doing so failed. Moral thinking nevertheless tends to focus on moral evil, since it is much more likely to be within human control than natural evil.

The primary subjects to which moral evil (simply 'evil' from now on) may be ascribed are human actions. Intentions, agents, and institutions may also be evil, but only in a derivative sense. For intentions are evil if they lead to evil actions; agents are evil if the preponderance of their actions are evil; and institutions are evil if they regularly prompt agents representing them to perform evil actions. In its primary sense, therefore, evil is connected essentially with causing serious unjustified harm to sentient beings, and since the means by which this is done are human actions, an account of evil should begin by concentrating on them.

It is clear that evil actions are widespread, and that they are responsible for much suffering. The obvious explanation of this fact is that human beings are motivated by greed, cruelty, envy, rage, hatred, and so forth, and evil actions are the manifestations of these vices. But this is unilluminating, unless it is combined with an explanation of why human beings possess and act on vices. To attribute vices to choice is a poor explanation, since many vices are the unchosen consequences of genetic predispositions and corrupting circumstances, and even if vices are the results of choices, the question of why vices rather than virtues are chosen remains (see Virtues and vices §4).

2 Evil as deviation from the good

The philosophically most influential explanation of evil is embedded in the Socratic view that no one does evil knowingly (see Socrates §6). The thought behind the apparently obvious falsehood of this claim is that human agents are normally guided in their actions by what seems to be good to them. The explanation of evil actions must therefore be either that the agents are ignorant of the good, and perform evil actions in the mistaken belief that they are good, or, while they know what the good is, they do evil unintentionally, through accident, coercion, or some incapacity (see Moral knowledge §1; Akrasia). The remedy for evil, consequently, is moral education that imparts genuine knowledge of the good and strengthens the intention to act on it.

This Socratic view, however, is driven to rely on a metaphysical assumption about the nature of reality and its effect on human aspirations. For, since human experience of the world testifies that thorough knowledge of the good and good intentions are compatible with evil actions, it must be supposed that human experiences disclose only appearances, not reality. The metaphysical assumption that needs to be made, therefore, is: first, that beyond human experiences of the world that appears to contain chaos and evil, there is a suprasensible true reality, in which a moral order prevails; and second, that good lives for human beings depend on learning to live in conformity to this order, rather than being led astray by deceptive appearances. Plato's Socrates explains evil, therefore, as a deviation from the good due to a human defect in cognition or intention that leads to mistaking appearance for reality.

This metaphysical assumption and the explanation of evil implied by it has passed from Greek thought to Christian theology chiefly through the works of Augustine and Aquinas. Christianity attributes to an all-knowing, all-powerful, all-good God the creation of the moral order that permeates reality, and it explains the prevalence of evil by the corrupting influence of original sin, which leads human beings to choose evil over the good, and thereby wilfully or weakly pit themselves against God's moral order (see Sin §2). Although Christian thinking about evil has dominated Western thought between the Greeks' time and ours, it nevertheless must be seen, if we ignore some twists and turns of theological sophistication, as a particular adaptation and elaboration of the metaphysical assumption and explanation of evil first advanced by Plato's Socrates.

This metaphysical assumption, however, cannot be reasonably maintained in the light of well-known objections, which can only be stated here without elaboration. First, any evidence that may be cited in favour of the supposed existence of a moral order in a supposed suprasensible reality beyond the world as it appears to normal human observers must be derived from the world as it appears to normal human observers, since, as a matter of logic, there is no other possible source of evidence. The evidence derived from appearances, however, cannot reasonably be taken to point to any suprasensible order in reality because the most such evidence can imply is that human knowledge of the world as it appears is limited and fallible. It is logically impossible for evidence to support inferences about what may lie beyond all possible evidence. Second, if, undeterred by this logical obstacle, defenders of the metaphysical assumption pursue their speculations about the implications of the evidence, they must recognize that evidentially unsupported implications can be derived both in favour of and against their assumption. If the existence of a moral order in suprasensible reality is inferred from observed instances of apparent goodness, then the existence of an evil order in suprasensible reality must be analogously inferrable from observed instances of evil. There is, consequently, no more reason to think of evil as deviation from the good than there is to think of the good as deviation from evil. Third, even if it is assumed for the sake of argument that the metaphysical assumption is defensible, it accounts only for moral evil, caused by human failure, and not for natural evil, whose occurrence cannot be attributed to human agency.

3 Evil as illusory

The Stoic-Spinozistic view attempts to avoid these objections by denying the reality of evil. It acknowledges that evil appears to exist, but its appearance is said to be an illusion to which human beings succumb through misdirected desires (see Spinoza 1677). Such desires cannot be satisfied because they are contrary to the moral order of reality, which need not be supposed to be suprasensible. If the misdirection of these desires is recognized, then the unavoidable experience of frustration they cause will be seen as emotional detritus that has been misidentified as evil. The advantage of the Stoic-Spinozistic view is that if evil were indeed illusory rather than real, then the objection to the Socratic view that it is incapable of explaining the reality of evil would be met (see Spinoza, B. de §10; Stoicism §19).

The Stoic-Spinozistic view is undoubtedly right in that what appears to be evil may not be and that greater self-knowledge and self-control make it possible to avoid much unnecessary suffering caused by mistaking for evil the frustration of misdirected desires. This view, however, is advanced not merely as a proposal for alleviating some instances of evil, but as an explanation of all evil. And as such, it is a failure for several reasons.

First, it cannot reasonably be held that all desires are misdirected, for human nature requires having and satisfying some desires. Rightly directed desires, however, are often frustrated, their frustration often results in serious unjustified harm, and that is real evil which cannot be alleviated by growth in self-knowledge and self-control. Second, the distinction between real and illusory evil rests on moral beliefs, which may be true or false. This view

is committed to holding that beliefs about the occurrence of evil are always false. For if some were true, not all evil could be illusory. If, on the other hand, beliefs about the occurrence of evil were always false, then the belief that torturing innocent people is evil, for instance, would also be false. It is, however, a precondition of morality, and indeed of civilized life, that such basic moral beliefs are regarded as true. The view that all evil is illusory, therefore, is incompatible with human nature, morality, and civilized life.

4 Evil as a contrast necessary for the good

Another attempt to account for evil is the Leibnizian view that recognizes its reality, but argues that the evil that exists is the minimum necessary for the existence of the good, which far outweighs the amount of evil there is (see Leibniz 1710). Evil is thus seen as the cost of the great benefits the good provides (see Leibniz, G.W. §3). The assumption behind this view is that the good could exist only in contrast with evil. But whatever is true of phenomena requiring contrasting aspects, it is not true of good and evil. It is absurd to suppose that there can be kindness only if there is cruelty, or freedom only if there is tyranny. Defenders of this view therefore tend towards an epistemological sense of the contrast: evil is said to be required so that the good could be appreciated as good. The difficulty with this is that even if a contrast were necessary for appreciation, drawing it would not require the existence of evil. The good could be properly appreciated even in contrast with imaginative depictions of evil. It is, for instance, unnecessary to have people actually drawn and quartered in order to maintain a lively appreciation of one’s good health. Nor is it required for the appreciation of the good that it be contrasted with evil, since the neutral or the indifferent would serve as a contrast just as well. People’s dying in their sleep, without being tortured to death, is sufficient to enhance one’s appreciation of the good of being alive.

5 Facing evil

It will perhaps be apparent that the various attempts to account for evil are not among the highest achievements of Western philosophy. All the surveyed accounts begin with the assumption that the good is primary and then vainly struggle to explain the prevalence of evil. It is hard to avoid the conclusion that the history of this subject is riddled with bad arguments and sentimentalism. A reasonable account of evil must acknowledge the reality and prevalence of evil. It must recognize that much evil that prevents the wellbeing of humanity is caused by human beings who are not moral monsters but ordinary people going about their ordinary lives. The character of such people includes virtues and vices, and a struggle between them (seeVirtues and vices §5). Depending on the hardships they face, the traditions and institutions that guide their conduct, and their capacity, opportunity, and motivation for moral reflection, sometimes their virtues and sometimes their vices prevail. Human nature is mixed; it is neither simply good, nor simply evil. It is primarily the proportion of the mixture, not the knowledge and intentions of agents, that determines how much evil will be caused by specific individuals in specific contexts. The search for a metaphysical explanation for this banal fact is a diversion from the morally necessary task of decreasing evil by improving the conditions and character of individual moral agents.

Evil, problem of

In this context, 'evil' is given the widest possible scope to signify all of life's minuses. Within this range, philosophers and theologians distinguish 'moral evils' such as war, betrayal and cruelty from 'natural evils' such as earthquakes, floods and disease. Usually the inescapability of death is numbered among the greatest natural evils. The existence of broad-sense evils is obvious and spawns a variety of problems, most prominently the practical one of how to cope with life and the existential one of what sort of meaning human life can have.

Philosophical discussion has focused on two theoretical difficulties posed for biblical theism. First, does the existence of evils show biblical theism to be logically inconsistent? Is it logically possible for an omnipotent, omniscient and perfectly good God to create a world containing evil? One classical response to this, following Leibniz, is to argue that such a God would create the best of all possible worlds, but that such a world may contain evil as an indispensable element. Alternatively, evil may be an unavoidable consequence of the boon of free will, or it may be part of a divine plan to ensure that all souls attain perfection.

The second difficulty for biblical theism is, even if we grant logical consistency, does evil (in the form, for instance, of apparently pointless suffering) nevertheless count as evidence against the existence of the Bible's God? One frequent theistic response here is to argue that the apparent pointlessness of evil may be merely a result of our limited cognitive powers; things would appear the same to us whether or not there were a point, so it is not legitimate to argue from the evidence.

1 Problems of evil

The so-called 'logical' problem of evil rests on the contention that the following two claims of biblical theism:

(I) God exists, and is essentially omnipotent, omniscient and perfectly good; and
(II) evil exists,

combine with the following plausible attribute analyses:

(P1) a perfectly good being would always eliminate evil so far as it could;
(P2) an omniscient being would know all about evils; and
(P3) there are no limits to what an omnipotent being can do,

to form an inconsistent quintet, so that the conjunction of any four entails the denial of the fifth; most notably the conjunction of (P1)-(P3) with either of (I) or (II) entails that the other is false.

Such an argument can be taken aporetically, as a challenge to propose more subtle alternatives to (P1)-(P3), but it has usually (in analytical philosophy of religion since the 1950s) been advanced 'atheologically' as an argument against the existence of God (see Atheism §4; Natural theology §5). Likewise important is the distinction between the abstract problem, which takes 'evil' in (II) to refer generally to some evil or other (say the pain of a single hangnail), and the concrete problem, which construes (II) as shorthand for the existence of evils in the amounts and of the kinds and with the distribution found in the actual world. While the abstract problem raises a question of conceptual interest, it is the concrete version that gives the issue its bite.

Bold responses deny (P3), maintaining variously that God cannot overcome certain natural necessities (like Plato's Demiurge), that he cannot conquer his evil twin (as in Manichean dualism), or even that he lacks the power to compel at all (see Process theism §2). Some reject (P2), observing that many evils arise from free choice, while future contingents are in principle unknowable (see Omniscience §4). (P1) is the most obviously vulnerable because it is contrary to the common intuition that ignorance and weakness excuse, and is best replaced with:

(P4) it is logically impossible for an omniscient, omnipotent being to have a reason compatible with perfect goodness for permitting (bringing about) evils.

Rebuttals seek to counterexemplify (P4) by identifying logically possible reasons available even to an omniscient, omnipotent God.

2 Logically necessary connections with greater goods

Since omnipotence is not bound by causally necessary connections, it is natural to look for reasons among the logically necessary connections of evils with greater goods. Because the piecemeal approach of correlating distinctive sorts of good with different kinds of evil (for example, courage with danger, forgiveness with injury) threatens to be endless, it seems advantageous to identify a single comprehensive good that logically integrates all ills. One promising strategy takes its inspiration from Leibniz and develops his 'best of all possible worlds' ('BPW') theodicy in terms of contemporary possible-worlds semantics (see Leibniz, G.W. §3; Modal logic, philosophical issues in §1). If a possible world is a maximal consistent state of affairs, each of infinitely many constitutive details is essential to the possible world of which it is a part. Assuming (P5) that possible worlds as wholes have values (P6) that can be ranked relative to one another and (P7) that the value scale has a maximum (P8) occupied by one and only one world, one can interpret divine creation in terms of actualizing a possible world and reason (P9) that necessarily an essentially omniscient, omnipotent and perfectly good God would actualize the best. Given the further controversial claim that:

(P10) the BPW contains instances of evil as logically indispensable components,

it follows that the desire to create the BPW is a reason compossible with perfect goodness for God not to prevent or eliminate all instances of evil.

(P10) contradicts our *prima facie* intuition that the BPW should be homogeneously good. Defenders of BPW approaches (see Chisholm 1968) distinguish two ways in which value-parts may be related to value-wholes. The one presupposed by the critics is simply additive: negatively and positively valued parts simply 'balance off' one another and the inclusion of any 'minuses' inevitably lowers the value total. By contrast, parts may be integrated into wholes by relations of organic unity, in such a way that the positive value of the whole may defeat the negative value of the part (for example, the way the beauty of Monet's design defeats the ugliness of some colour patches). (P10) envisages the defeat of evil within the context of the possible world as a whole.

Leibniz thought he could prove the necessity of (P10) on the basis of his a priori arguments for the necessity of (I) and (P9); he believed that (P10) followed from the fact that God had actualized this world. Yet (P10) seems to fall into that class of propositions that are logically possible if and only if logically necessary. Those who recognize no sound demonstrations of (I) are left to claim that (P10) is epistemically possible. Since the atheologian is in the same epistemic predicament with respect to (P10), this epistemic defence would be sufficient *ceteris paribus* to discharge the burden of proof imposed on the theist by the argument from evil.

This BPW approach makes several other debatable value-theory assumptions. Augustine's notion (*contra* P8) that many alternative worlds have maximum value imposes no damage. Aquinas' insistence (*contra* P7) that for every collection of creatures there is a better one would not be crippling if every possible world above a certain value-level included evil. The rejection of (P5) and (P6), however, would be fatal for BPW approaches. Some question whether our comparative evaluations of small-scale states of affairs (for example, Jones' enjoying a symphony as better than his experiencing excruciating pain) is good evidence that the values of maximal states of affairs form a hierarchy. More fundamentally, some have argued (*contra* P5) that states of affairs are not intrinsically good or bad, although they can be good or bad for certain persons or projects and can ground different moral evaluations by particular agents. Anti-consequentialists in ethics also challenge whether (P9) follows from (P5)-(P8) (see Consequentialism). Deontologists would let justice to individuals trump putative increases in the value of states of affairs (see Deontological ethics). Could creating the BPW be a reason compossible with perfect goodness for permitting suffering and degradation for the relatively innocent? Even if such value-maximizing were compatible with perfect goodness, it is not obviously required. For example, divine goodness is often interpreted as grace, a disposition to show favour independently of merit.

Finally, this modified Leibnizian approach entails divine determinism, because in choosing which of infinitely many fully determinate possible worlds to actualize, God is deciding on each and every detail. Some find this theologically objectionable, either because it seems incongruous for God to hold created persons responsible to himself for actions he determined, or because it fails to put enough distance between evil and divine aims.

3 Free-will defences

The last-mentioned worries are well accommodated by the other main traditional theme - that (some or all) evil originates in the wrong or evil choices of free creatures. Free-will approaches contend that:

(A1) created free will is a very great good, whether intrinsically or as a necessary means to God's central purposes in creation;
(A2) God cannot fulfil his purposes for and with free creatures without accepting the possibility that some will misuse their freedom, thereby introducing evil into the world.

In classical developments of this defence, (A1) is supposed to be a reason compossible with perfect goodness for making free creatures, while (A2) is compatible with the claim that evil is not necessary to the perfection of the universe or any other divine purpose. Some or all evil is not something God causes or does, but something he allows, a (perhaps) known but unintended side effect of his aims. The introduction of evil into the world is explained by the doctrine of 'the Fall', according to which God made angelic and human free agents in naturally optimal condition and placed them in utopian environments. God wanted them freely to choose what is right or good, but some angels and the primordial humans Adam and Eve chose what is wrong, thereby actualizing the possibility of evil.

Contemporary attention (beginning with Plantinga) has turned away from free-will defences based on the principles of double effect and doing-allowing - the principle that agents are not as responsible for the known but unintended side effects of their actions as they are for their chosen means and ends; that they are not as responsible for what they allow as for what they do - to others that reconnect with possible-worlds semantics (see Double effect, principle of). Once again, God creates by actualizing a possible world, but freedom is now taken to be incompatible with determinism, with the consequence that God and free creatures collaborate in determining which possible world becomes actual. Created freedom does not so much 'distance' God from evils as limit which worlds God can create. As with BPW approaches, God evaluates possible worlds as to their global features - (P5) and (P6) are assumed true, although not necessarily (P7) and (P8) - but this time he evaluates those that are a function of created incompatibilist-free choice: for example, a very good world with the optimal balance of created moral goodness over moral evil.

In defence of (A2), both classical and possible-worlds approaches appeal first to the notion that not even God can cause someone else's incompatibilist-free choices. To the objection that God should use his foreknowledge to actualize only incompatibilist-free creatures who will never sin, free-will defenders reply that such foreknowledge is not prior in the order of explanation to God's decision to create. To the suggestion that God should use his middle knowledge of what free creatures would do in particular circumstances, some (notably Plantinga 1974) grant that such counterfactuals of freedom can be true, but argue that it is logically possible that all incompatibilist-free creatures be 'transworld depraved' - that is, that no matter which combinations of individuals and circumstances God actualized, each would go wrong at least once - and logically possible that any world containing as much moral goodness as the actual world would also include at least as much moral evil as the actual world contains. Thus, it is logically possible that God could not create a world with a better balance of moral good over moral evil - which would be a reason compossible with perfect goodness for his not doing so.

This ingenious argument is controverted both by those who agree and those who deny that counterfactuals of freedom can be true. Among the former, Suárez (§1) defends middle knowledge but arguably finds transworld depravity impossible because of God's necessary resourcefulness, which he takes to have the following implication: necessarily, for any possible person and any situation in which they can exist, there are some helps of grace that would (should God supply them) win the creature over without compromising its incompatibilist freedom. Others (notably R.M. Adams 1977) wonder what could make such counterfactuals true about creatures considered as merely possible. Incompatibilist freedom rules out divine choices or any native features of the creative will. To appeal to a contingent condition (*habitudo*, or primitive property) independent of both is too close for comfort to the ancient doctrine of fate that falls alike on the gods and their creatures, and contradicts traditional Christian views of divine providence (see Providence §1). To maintain that counterfactuals of freedom are true although there is nothing to make them true violates a correspondence theory of truth (see Truth, correspondence theory of). Denying truth to such counterfactuals of freedom does not automatically put (A2) clear of the objection from omniscience, however, if God could know about merely possible creatures what they probably would do in any given circumstance. But the meaning and ground of such probability assessments is at least as problematic as

that of the original counterfactuals (see R.M. Adams 1977, 1985).

Even if (A2) were unproblematic, it could still be asked whether (A1) necessarily constitutes a reason compossible with perfect goodness for allowing evils. Two dimensions of divine goodness may be distinguished: ‘global’ goodness and goodness to individual created persons. The possible-worlds approaches cite global features - ‘the best of all possible worlds’, ‘a world a more perfect than which is impossible’, ‘a world exhibiting a perfect balance of retributive justice’, ‘a world with as favourable a balance as God can get of created moral good over moral evil’ - by way of producing some generic and comprehensive reason for allowing evil. But worlds with evils in the amounts and of the kind and with the distribution found in the actual world contain horrendous evils - evils the participation in (the doing or suffering of) which gives one *prima facie* reason to doubt whether one’s life could (given their inclusion in it) be a great good to one on the whole - unevenly distributed among humans and uncorrelated with variations in desert. Even if horrors thus apportioned were epistemically compatible with global perfections, these defences of divine goodness as a producer of global perfection would not so much guarantee as raise doubts about God’s goodness to individual participants in horrors. Divine goodness to them would require God to defeat the disvalue of horrors not only within the context of the world as a whole, but also within the framework of the individual participant’s life. Nor will precise individual retribution fit this bill where the perpetrators of horrors are concerned. ‘Balancing’ horror with horror only deepens the difficulty. Some Christians bite this bullet, insisting that decisive defeat of evil is promised only to the obedient, while the wicked can expect the reverse, a decisive defeat of positive meaning in their lives in the form of eternal damnation. Others insist that the doctrine of hell only makes matters worse by giving rise to a specialized version of the problem of evil (see Hell).

4 Divine goodness to creatures

Soul-making theodicies try to fill the explanatory gap regarding divine goodness to individual created persons by adding further hypotheses as to what they might get out of existence in an environment in which they are so vulnerable to sin, suffering and horrors. Some versions stipulate:

(A3) God’s purpose in creation culminates in a process of spiritual development in which autonomous created persons with their own free participation are perfected, and transformed from self-centred to other-centred, God-centred, Christlike or otherwise virtuous souls; and
(A4) environmental evils are permitted because they create an environment favourable to soul-making.

(A3) is compatible both with the notion that humans are initially created with mature unobstructed agency and so are fully responsible for their choices, and with the alternative idea (retrieved from Irenaeus by Hick (1966)) that human agency began immature, so that sin was to be expected in the course of the ‘growing-up’ process. The idea is that life in a world with evils such as this is, or with created cooperation can be, ‘good for the soul’.

Establishing (A4) is difficult thrice over because: (i) the task shatters into piecemeal cataloguing, with separate demonstrations for each sub-type of environmental evil; (ii) relevant necessary connections with the soul-making environment can be hard to show; and (iii) experience makes it *prima facie* implausible that a world with evils such as ours is a good classroom for the soul. In response to (ii), some (notably Hick 1966) ingeniously contend that ‘dysteleological’ evils lend an air of mystery which is itself favourable to soul-making. Others (for example, Stump 1985) modify (A4) to acknowledge that some environmental evils are consequences of sin.

Where God’s soul-making purpose succeeds, it is easy to see how the painful journey is worth the individual’s while. What about where it fails? Some (especially Swinburne 1983) reply that the dignity of self-determination is enough, whatever the outcome. The credibility of this contention varies with one’s estimate of the robustness of human nature as well as one’s conception of the natural or punitive consequences of repeated bad choices. Pessimists argue that ante-mortem participation in horrors makes a mockery of human self-determination; *a fortiori*, so does decisive personal ruin in hell.

Others (notably Hick 1966) embrace a doctrine of universal salvation: if ante-mortem horrors remain undefeated between birth and the grave, education will continue after death, probably in a series of careers, until the soul is perfected and brought into intimacy with God. Thus, God does guarantee each created person an overall existence that is a great good to them on the whole, one in which participation in horrors is balanced by the incommensurate

goodness of intimacy with God. Are such horrors likewise defeated within the context of the individual's existence? The stout of heart might say 'yes', because participation in horrors that remain undefeated within the individual's ante-mortem career contributes to the sense of mystery that makes a positive contribution to the soul-making of others. Since one is at least the agent-cause of the willy-nilly sacrifice of one's ante-mortem good, participation in horrors would constitute some sort of shift from self- to other- or God-centredness after all. Even if this putative positive dimension of participation in horrors is swamped by its negative aspect when considered within the framework of the individual's ante-mortem career, it provides a means for participation in horrors to be integrated into the overall development that gives positive meaning to the individual's life and thus defeated within the context of the individual's existence as a whole.

Some (notably M.M. Adams) contend, on the contrary, that divine goodness to created persons would do more to lend positive meaning to any careers in which they participate in horrors. The sacrifice involved in participation in horrors is pedagogically inept as a first lesson because it can damage the person so much as to make much further ante-mortem progress from self- to other- or God-centredness virtually impossible. This combines with the delay in gratification to another or perhaps many lives later to de-emphasize the importance of this life, leaving the impression that it would have been better skipped by those whose spiritual development was significantly set back through participation in horrors. To give this life, or any career involving participation in horrors, positive significance, some parameter of positive meaning other than contribution to soul-making must be found. Given two further assumptions - that divine metaphysical goodness is infinite, and that intimacy with God is incommensurably good for created persons - the mystical literature suggests several ways for participation in horrors to be integrated into the created person's relationship with God, ranging from divine gratitude for one's earthly career to various types of mystical identification between God and creatures in the midst of horrors. Because the identification occurs in this life and divine gratitude is for this life, they add positive significance to this life even where the creature has no ante-mortem but only postmortem recognition of these facts.

5 Methodological notes

Much contemporary discussion of BPW and free-will defences has addressed itself to the logical problem of evil because we seem epistemically in a better position to assess the compossibility of logically possible reasons with various conceptions of perfect goodness than to pronounce on what God's actual reasons are. In identifying logically possible defeaters, many of the earlier discussions (including those by Pike (1963) and Plantinga (1974)) confine themselves to a religion-neutral value theory, the better to answer the atheologian on their own turf. By contrast, soul-making, mystical and other explanatory theodicies draw on the resources of revelation for their speculations about God's actual reasons for the evils of this world and usually address their remarks in the first instance to the believing community. The distinction between these approaches blurs when attention is riveted on the concrete logical problem of evil - that is, on the logical compossibility of God with evils in the amounts and of the kinds and with the distribution found in the actual world. In so far as the consistency of actual religious belief is at stake, it becomes highly relevant to test the reasons supplied by revelation for logical compossibility with the existence of evils and the goodness of God. Where they pass, they can be advanced as solving the concrete logical problem of evil, whether or not their truth can be proved to the atheologian.

Once the wider resources of the religions under attack are allowed to interpret (I) and (II), it becomes clear that explanatory reasons come in two broad types: reasons why God causes or permits evils, and does not prevent or eliminate them; and explanations as to how God could be good to created persons despite their participation in evil. Reasons-why identify some great-enough good with which evils are necessarily connected, while reasons-how specify ways God could defeat evils in which the created person has participated and thus give that person a life that is a great good to them on the whole. Much philosophical discussion (Swinburne is particularly insistent on this point) presupposes that the problem cannot be solved without sufficient reasons-why. The criticized religions arguably take a mixed approach. Assuming that what perfect goodness can permit or cause is a function of what it can defeat, they combine partial reasons-why with elaborate scenarios by which God defeats even the worst horrors.

6 The evidential problem of evil

Recently many philosophers (notably Rowe, Alston, van Inwagen and Wykstra) have concluded that the most serious version of the problem of evil concerns not the logical but the evidential relation between (I) and (II). The

mere logical possibility that a student has broken all four limbs and been hospitalized for a heart attack will win them no extension of essay deadlines if the tutor can see that the student is in fact physically sound. Likewise, the evidential argument contends, many actual evils - such as the slow, painful death of a fawn severely burned in a forest fire started by lightning - appear pointless, in the sense that our composite empirical evidence constitutes strong reason to believe they have no point. But an omniscient, omnipotent being could have prevented some of them, while a perfectly good being would not allow or cause any of them it could avoid. Therefore, (II) concretely construed constitutes decisive evidence against (I).

Once again, replies could take the piecemeal approach, trying to show for each type of very intense suffering that it has a discernible point after all. It would not be necessary to complete the process to undermine the evidential argument. Success with some important cases would increase the probability that defeating goods are also present in other cases where we have not discovered any (see Suffering §4).

The favourite response (for example, by Wykstra, Alston and van Inwagen) attacks the argument at its epistemological foundations. The contention is that our composite empirical evidence could constitute strong reason to believe some actual evils pointless only if our cognitive powers would afford access to any point such evils might have were they to have one. If things would seem roughly the same to us (that is, if our evidence would be roughly the same) whether or not such evils had a point, the fact that we detect no point is not good evidence that there is no point. In particular, we are in no position to see that many instances of intense suffering are not explained by some of the reasons appealed to in traditional theodicies.

Defenders of the evidential argument (notably Rowe) grant the appeal of the underlying evidential principle, but relocate the disagreement in the richness of the theological hypothesis on which one draws. They argue that if one restricts oneself to a straightforward philosophical reading of (I), then it is likely that the situation with regard to intense suffering would be different in ways discernible by us. Expanded theism might import assumptions about the hiddenness of divine providence, mystical identification with suffering creatures, etc., but deploying these resources in the evidential debate carries a cost, because the prior probability of expanded theism is lower than that of (I).

This last point holds only if the richer theological theory is advanced as true. If instead it is used, as with the logical problem, to generate possible - this time not merely logically but epistemically possible - explanations, then no dilution in prior probabilities need be accepted. And once again, the more epistemically possible explanations there are, the greater the probability that the suffering in question is not pointless.

Evolution and ethics

The fact that human beings are a product of biological evolution has been thought to impinge on the study of ethics in two quite different ways. First, evolutionary ideas may help account for why people have the ethical thoughts and feelings they do. Second, evolutionary ideas may help illuminate which normative ethical claims, if any, are true or right or correct. These twin tasks - explanation and justification - may each be subdivided. Evolutionary considerations may be relevant to explaining elements of morality that are culturally universal; they also may help explain why individuals or societies differ in the ethics they espouse. With respect to the question of justification, evolutionary considerations have sometimes been cited to show that ethics is an elaborate illusion - that is, to defend versions of ethical subjectivism and emotivism. However, evolutionary considerations also have been invoked to justify ethical norms. Although there is no conflict between using evolution both to explain traits that are universal and to explain traits that vary, it is not consistent to claim both that evolution unmasks ethics and *justifies particular ethical norms.*

1 Explanation

Before we can assess whether evolution helps explain why we have the ethical beliefs we possess, we need to be clear on what the phenotype in question is. What part of human culture is delimited by the term ‘ethics’?

Some of the evaluations an organism may place on an action or a person or a motive may count as ethical in character. What makes an evaluation ethical? The question here is not the normative question, ‘What standards *should* an individual use?’ Rather, it is descriptive; its answer helps define a line of inquiry in the social and natural sciences. If we visited an alien society - either that of human beings or of some other species - how would we tell whether that society has an ethics?

Even if the individuals concerned have altruistic motives, this does not show that they possess an ethics. Parents may care for the welfare of their children, but feeling love and concern are not the same as possesing a morality. Closer to the mark is the idea that an ethics is a set of principles that possesses a certain sort of generality (see Morality and ethics).

In his *Methods of Ethics* (1874), Sidgwick suggested that it is a self-evident truth of common-sense morality that if one person has a right to do something, then so does anyone else who is similarly situated. This normative claim has a descriptive analogue: an organism has a morality only if it possesses a set of principles that dictate what anyone fitting a certain qualitative description is entitled or required to do. These principles need not provide an algorithm for deciding which actions are morally right; they simply may specify a set of ethically relevant considerations. Nor does this idea require that a morality treat all human beings as having equal ethical standing. Tribal moralities, no less than universal moralities, state what individuals must be like to be entitled to perform various actions. Nor does the Kantian pedigree of the idea mean that ethics focuses exclusively on disinterested reason and has nothing to do with engaged emotion (see Kant, I. §§9-10); an ethics of caring about personal relations may still find expression in a set of general principles.

Although generality is arguably a necessary feature of a morality, it is not sufficient. The hypothetical imperatives that specify rules for different aspects of cultural practice - of etiquette, of sports, and so on - may also be general. Ethics may be special because it dictates what individuals ought to care about, no matter what else they happen to want.

Even after we single out the aspect of a culture that falls under the rubric of ‘ethics’, we must take care to describe this phenotype accurately. A person’s or a society’s ethics may fail to coincide with the slogans that figure in public discourse. Aliens visiting Earth from another galaxy would make an enormous mistake if they thought that the people who pay homage to the Ten Commandments believe that the acts listed are always prohibited or always required. An ethics may be compared to a grammar; just as people speak a language without being able to articulate the grammatical principles their language obeys, so their ethical intuitions correspond to a set of principles that they often are unable to articulate. Descriptive ethics poses problems that are no less subtle than those addressed in theoretical linguistics.

Regardless of how exactly a morality is defined, the fact that moralities are so common in human societies raises a

fundamental evolutionary puzzle. An individual may possess a mixture of selfish and altruistic motives without having a morality. Why, then, do moralities exist? It is worth considering the possibility that moralities began life and continue to exist because they perform a certain social function. The idea that there are obligations, prohibitions and entitlements that people must respect regardless of whatever else they happen to want obviously contributes to a well-functioning society. Perhaps everyone benefits from a society in which a morality is present; alternatively, it may be that some benefit at the expense of others. Each of these patterns can be accommodated in an evolutionary explanation of why morality emerged as a social form in ancestral populations.

In addition to asking why moralities exist, evolutionary theory can be asked to explain why moralities have the features they do. But here we must be careful. To ask whether evolution can explain ‘our ethics’ is to begin with a poorly formulated problem. There are many features of the ethical norms endorsed by a person or a society. Some of these may have important connections with evolutionary considerations; others may not.

In virtually every human society, killing a member of one’s own society is viewed as a morally more weighty act than killing a chicken. It is hard to believe that evolution is irrelevant to why this is so. On the other hand, the fact that many societies have changed their views about capital punishment in the last century may be explicable by cultural, rather than evolutionary, factors.

This is not to deny that having views about capital punishment requires an organism to have a big brain, and that having a big brain is a product of evolution. The point remains, a big brain is something that people of today share with their ancestors of a hundred years ago; thus it does not explain why our views on capital punishment differ from those held a few generations ago.

The present example about the ethics of killing should not be taken to imply that evolution can help explain only those features of ethics that are culturally universal. Evolution has endowed human beings with enormous behavioural plasticity; however, sometimes the details of an organism’s plasticity are themselves dictated by evolution. For example, polar bears grow thick fur when it is cold and thinner fur when it is warm; natural selection has made the organism’s phenotype respond to environmental changes in ways that maximize fitness. So the mere fact that human beings espouse different ethical systems in different cultures does not imply that evolution is irrelevant to understanding that variation. The question is whether the pattern of variation can be understood as a phenotypically plastic adaptation.

2 Genetic arguments

If morality emerged and persisted because it conferred some evolutionary benefit, then we may speculate that morality would have had this utility even if there really were no such things as the obligations and rights that people objectively possess. It is worth remembering that ethics and religion were closely connected in the histories of many societies. Although Western philosophy since the Greeks prominently featured the idea that ethical principles have a status independent of divine decree, this declaration of independence is hardly a cultural universal. If theism emerged and persisted for reasons having nothing to do with its objective correctness, one may ask whether the same is true of moral convictions.

Here we find the beginning of a genetic argument for ethical subjectivism. The idea is that the causes of a conviction - the factors that generated it - provide evidence about whether the conviction is true. Arguments to this effect are called genetic because they refer to an idea’s genesis; they need have nothing to do with chromosomes. The question we need to consider is whether the fact that ethical beliefs can be explained - either by evolution or by details concerning human culture - show that these beliefs are never true or right or correct.

We must be careful not to dismiss this suggestion simply by invoking the so-called ‘genetic fallacy’. To be sure, one cannot deduce that a proposition is false just from information concerning why someone came to believe it. Even if Kekulé first thought of the benzene ring while he was hallucinating, this does not prove that benzene is not a ring.

Even so, facts about the genesis of a belief can provide non-deductive evidence about whether the proposition believed is true. If you form your belief concerning how many planets there are by drawing a number at random from an urn, then your belief is probably mistaken. The *process* of belief formation provides an indication of whether its *product* is likely to be correct.

If evolution produced some of the ethical convictions we have, what does that show about whether those convictions are likely to be true? Is this fact about their genesis evidence that the beliefs are false? It is easy to see how a genetic argument could show that a specific ethical belief is probably mistaken. If your belief about the number of planets can be cast in doubt by a genetic argument, there is no reason why your ethics should be immune from this challenge.

What is more puzzling is how the whole status of ethics as a subject can be undermined by genetic considerations. In the case of your belief about the number of planets, we assume that there is a fact of the matter concerning how many planets there are. We further assume that the process of drawing a number at random from an urn is not connected in the right way to that fact. This set of background assumptions explains why we are entitled to be confident that your belief about the number of planets is probably untrue.

For a genetic argument to support ethical subjectivism, it would have to be shown that the process of evolution is completely unrelated to the factors that make an ethical proposition true or false. But even if this could be demonstrated, it would not follow that no normative statements are true, only that the ones we happen to espouse are probably mistaken. How could a genetic argument support the conclusion that ethics, in its entirety, not just in the details we happen to believe now, is an illusion? Subjectivism and emotivism, if they are to be defended, must be defended by some other route (see Moral Scepticism).

3 The is/ought distinction

Hume (§4) famously observed that a normative conclusion cannot be deduced validly from purely descriptive premises. One cannot derive an *ought* from an *is*. This claim is not undermined by the fact that terms in natural languages sometimes combine normative and descriptive elements. To say that someone is cruel is both to describe and criticize the person in question. However, that does not affect the Humean thesis.

It follows from this Humean doctrine that descriptive facts about evolution cannot be sufficient to deduce normative conclusions. The fact that human beings in ancestral populations were omnivores does not provide an ethical justification for eating meat. It is ‘natural’ for human beings to eat meat, in the sense that this is a trait that is found in nature. Nothing normative follows from this point.

The Humean thesis concerns deduction. Even if an ought-statement cannot be deduced from purely is-premises, the question remains of whether descriptive premises provide non-deductive support for normative conclusions. Here the Humean thesis should be extended to the domain of non-deductive inference; purely is-premises do not, by themselves, provide evidence for an ought-conclusion.

It does not follow that evolutionary information is always irrelevant to ethical problems. Evolutionary facts may be relevant, even if they do not provide the whole story. Whether this is so depends on the specific ethical system one considers and on the details of the ethical problem at hand. In just the same way, human psychology is relevant to ethics only in so far as some ethical theory makes this so. For example, hedonistic utilitarianism says that an action’s moral standing is determined by its propensity to cause pleasure and pain. If psychology tells us about the pains and pleasures that an action is apt to cause, this information is ethically relevant because utilitarianism (or some other ethical theory of interest) says that it is.

One ethical idea that has been thought to establish the relevance of evolution to ethics is the ‘ought-implies-can’ principle. This principle says that obligations encompass only what is possible; we are not obliged to perform actions that are impossible for us to perform. If evolutionary considerations establish that certain types of behaviour are outside the human repertoire, then the idea of requiring them would not only be hopelessly utopian - such reforms also would fail to be ethically imperative.

This concept sometimes surfaces in discussion of the idea that natural selection will lead females to evolve the inclination to be more choosy about their sexual partners than males; females may have more to lose in fitness terms by making a poor choice. If evolution has hard-wired a sexual double standard into our ethical intuitions, then it will be false that we ought to change the way we think. However, a moment’s reflection shows that a double standard does not strike all people everywhere as obviously correct. For many species, natural selection has forged the details of behaviour; but for human beings, it has caused a big brain to evolve. This big brain allows us to reflect on what would be for many other species an automatic reflex. Paradoxically enough, natural selection has

caused a trait to evolve in human beings that limits the hegemony of natural selection in determining human behaviour. The human brain is a monkey wrench of the first order; apparently, it frequently prevents the ought-implies-can principle from demonstrating that evolutionary theory has a great deal to say about what our obligations are.

Still, ethics since Aristotle has repeatedly found attractive the thought that reflection on the biological nature of human beings must yield important information concerning what human flourishing amounts to, and a conception of human flourishing must be an important tool in forging theories of the right and the good. The more appealing such theories become, the more relevant to ethics will evolutionary ideas appear. There is no way to settle, once and for all, what evolution can teach us about ethics. As ethical theory evolves, the relevance of evolution will also experience a continuing metamorphosis.

Evolution, theory of

The biological theory of evolution advances the view that the variety and forms of life on earth are the result of descent with modification from the earliest forms of life. Evolutionary theory does not attempt to explain the origin of life itself, that is, how the earliest forms of life came to exist, nor does it apply to the history of changes of the non-biological parts of the universe, which are also often described as 'evolutionary'. The mechanisms of natural selection, mutation and speciation are used in evolutionary theory to explain the relations and characteristics of all life forms. Modern evolutionary theory explains a wide range of natural phenomena, including the deep resemblances among organisms, the diversity of life forms, organisms' possession of vestigial organs and the good fit or 'adaptedness' between organisms and their environment.

Often summarized as 'survival of the fittest', the mechanism of natural selection *actually includes several distinct processes. There must be variation in traits among the members of a population; these traits must be passed on from parents to offspring; and the different traits must confer differential advantage for reproducing successfully in that environment. Because evidence for each of these processes can be gathered independently of the evolutionary claim, natural selection scenarios are robustly testable. When a trait in a population has arisen because it was directly selected in this fashion, it is called an* adaptation*.*

Genetic mutation is the originating source of variation, and selection processes shape that variation into adaptive forms; random genetic drift and various levels and forms of selection dynamic developed by geneticists have been integrated into a general theory of evolutionary change that encompasses natural selection and genetic mutation as complementary processes. Detailed ecological studies are used to provide evidence for selection scenarios involving the evolution of species in the wild.

Evolutionary theory is supported by an unusually wide range of scientific evidence, gaining its support from fields as diverse as geology, embryology, molecular genetics, palaeontology, climatology and functional morphology. Because of tensions between an evolutionary view of homo sapiens *and some religious beliefs, evolutionary theory has remained controversial in the public sphere far longer than no less well-supported scientific theories from other sciences.*

1 Basics of evolutionary theory

According to the biological theory of evolution the variety and forms of life on earth are the result of descent with modification from the earliest forms of life. The theory does not attempt to explain the origin of life itself (see Life, origin of), nor does it apply to the history of changes of the non-biological parts of the universe, which are also often described as 'evolutionary'. A number of European thinkers in the seventeenth and eighteenth centuries advocated an evolutionary view of life, but it is Charles Darwin and Alfred Russel Wallace who offered the mechanism, *natural selection*, which is accepted as a primary process by which evolutionary change is effected.

At the time of the proposals of evolutionary theory presented in Darwin's book, *On the Origin of Species* (1859), and Wallace's article 'On the tendency of varieties to depart indefinitely from the original type' (1858), there was no adequate naturalistic (non-miraculous) explanation for the diversity of life forms, their adaptations to their environments, their possession of vestigial organs, the resemblances among them, or their history. Evolutionary theory gives unified and naturalistic explanations for these features of life and for a wide range of other biological phenomena.

The problem of mechanism in evolutionary biology is to explain how the originating group of organisms has led, through descent with modification, to other groups of organisms with very different characteristics from those of the ancestral group. The mechanism of natural selection requires a particular type of set-up: in the standard case, the organisms in a particular population must vary among themselves in some trait that is important to surviving and reproducing in their environment; the differences in that trait must be inheritable to some degree; and the different versions of the trait must actually make a difference in that environment to the success of reproducing and raising offspring to reproductively successful adulthood. Given this set-up, and given the continual importance of that feature of the environment which advantages some versions of the trait over others, the result is change in the traits of the population over time, that is, evolutionary change.

A simple illustration: take a population of brown bears living in the Arctic. They vary in the darkness of their fur, and their offspring tend to resemble their parents in fur colour. Most importantly, they are hunters living in an environment with little cover; prey find it more difficult to escape those with lighter fur, as they see these predators less well against the arctic landscape. Hence, those bears with lighter fur will on average be more successful in hunting, less likely to starve, more likely to reproduce and provide for their young than are those with darker fur. Over tens of thousands of generations of this cyclic process, this population of bears will become lighter and lighter in colour. Note that this explanation assumes a number of facts: heritable variations in fur colour continue to arise; the bears choose to stay in an arctic environment; the arctic environment itself remains snowy and icy for a significant portion of the year; and the prey populations continue to respond differently to lighter and darker predators.

The basic selection process incorporates several distinct biological processes, including heredity, reproduction and the production of variation, as well as the ecological and behavioural processes involved in differential survival and reproduction. Each of these components of evolutionary theory has been investigated, developed and empirically confirmed. Perhaps the most significant successes have been in the science of genetics, which gives accounts of mutation and genetic recombination as causes of the variation on which selection acts, as well as offering insight into the mechanisms and measurements of genetic drift. The most serious deficiency of Darwin's own view of evolutionary change was its lack of a well-confirmed theory of heredity and variation. Modern genetics has provided that theory, and has become a thriving science since the discovery of the structure of the hereditary material, DNA, by Francis Crick and James Watson in 1953. The discovery and investigation of the basic biochemistry of heredity, involving DNA and RNA, has confirmed the similarities among living things at the most fundamental levels, and has also led to huge bodies of evidence that can be used to compare and differentiate lineages (see Genetics; Molecular biology).

The modern view is not that every detail of evolutionary change can be attributed to natural selection within species; genetic drift, in which forms fluctuate or persist by chance, also leads to substantial genetic variation within and among species. Evolutionary phenomena, then, are understood as consequences of the actions of drift and selection on various levels of biological entities, including genes, organisms and groups of organisms.

Moreover, the existence of mutation and the operation of natural selection do not, by themselves, suggest that new species could arise, nor do they account for the increased diversification of species that we see in the history of life. Given only the facts mentioned in the scenario, our white bears, considered above, will not necessarily comprise a new species of bear. Thus, some attention to the nature of speciation is needed.

Darwin suggested that speciation occurred when there was relatively rapid change in the environment; these different environmental pressures, operating on variations that arose over the generations, could eventually result in a divergence of the descendent group from the ancestral one that was substantial enough that they could or would no longer interbreed. Thus, reproductive isolation is considered a primary cause and result of speciation in sexually reproducing species.

Ernst Mayr, a leading evolutionary biologist, has emphasized a crucial conceptual change (1982) that was involved in changing to the modern evolutionary view of life, namely, the switch from '*typological*' thinking - or thinking of organisms and species in terms of their essences or basic types - to '*population*' thinking, in which species are irreducible populations of unique individual organisms, and in which the *variability* among individuals is of the most fundamental importance. The difference between the evolutionary view of species and the essentialist view is thus not primarily that evolutionary species change over time, while essentialist species do not. Individual organisms in modern evolutionary theory are not members of their species in virtue of their sharing some basic group of properties or traits, or because they belong to a particular type or have certain features. On an evolutionary view of species, each organism is unique in its non-trivial properties, and there is no average type or typical specimen of any species. This is not to say that particular individuals cannot exhibit some calculated average height, colour or weight; the point is rather that all such averages over individuals must be interpreted as abstractions, and not even as temporary essential features of that species (see Species).

Developments in evolutionary genetics helped to clarify the importance of thinking in terms of populations. Mathematical population genetics, first developed by R.A. Fisher, J.B.S. Haldane and Sewall Wright, explored mathematically the issue of which evolutionary changes are possible under what conditions and how quickly

genetic change could occur. They examined the relative effectiveness and roles of mutation and selection in evolutionary change and, generally, developed models of evolution under a wide variety of conditions and assumptions.

In the late 1930s and early 1940s a general approach called ’the evolutionary synthesis’ expressed the newly united views of population geneticists, systematists and palaeontologists. Genetic mutation was seen as the originating source of variation, and selection as the shaper of that variation into adaptive forms; random genetic drift and various levels and forms of selection dynamic developed by the geneticists were integrated into a general theory of evolutionary change that encompassed both natural selection and genetic mutation as complementary processes. Detailed ecological studies were used to provide evidence for selection scenarios involving the evolution of species in the wild. Subsequently, synthesis of the fields of population genetics and ecology created the field of population biology, which studies such phenomena as population dynamics and ecological diversity in their effects on the genetic characteristics of populations.

In sum, contemporary evolutionary biology addresses a broad range of issues, all involving processes that produce key aspects of living beings, including their history, forms, functions, distribution, and their ways of earning a living and reproducing. Evolutionary explanations involve an interlacing of theories and evidence from an array of scientific subfields, including molecular and population genetics, anatomy and morphology (the study of life forms), palaeontology and ecology.

2 The nature of the supporting evidence

Darwin’s evolutionary claims involve two central theses: that present and past forms of life are all descended from one or few primitive life forms (descent with modification); and, second, that a primary mechanism of evolutionary change is the mechanism of natural selection. The major kinds of evidence supporting each of these claims are reviewed in this section.

Descent with modification. The field of palaeontology provides some of the most important evidence for descent with modification. In Darwin’s time, geologists recognized that there are patterns of geological formations which are parallel the world over, each containing distinctive sets of fossil species; these patterns helped establish the progression of the history of life. Two features of the fossil record were especially important: the fact that each animal and plant form appeared at certain times and certain places only, showing a pattern of increased diversification of life forms; and the evidence that extinction occurred. Moreover, the more ancient a form was, the more markedly it differed from living forms, and fossils from adjacent formations resemble one another far more than those from formations remote in time. The geographical distribution of fossils was also significant; extinct forms on a continent are closely related to living forms there. All of these facts support the view that the extinct forms of life are the ancestors of the living ones, and that modifications in form resulted in the diversification of life.

Morphology, the study of plant and animal form, also provides vital support for descent with modification. All mammals share a common form - as do all birds, all fish and all insects. These basic anatomical similarities within groups are evidence that they descended from a common ancestor. Admittedly, there are variations within the basic form: a bat’s arms now appear as wings, while a dog’s forelegs and a chimpanzee’s arms - defined as ’homologous’ because they are derived from the same character of the mammalian ancestor - serve for running and climbing respectively. The fact that a wide variety of forms of forelimb are variations on a common pattern is evidence that a common ancestral population evolved and diversified. Microstructures of organisms can also serve as evidence for evolution. The fact that cells share many basic structural properties across all plants and animals provides evidence for genealogical affinities among organisms. Perhaps most powerfully, the structure of some macromolecules, for example, specific proteins, has been useful in determining the relations among different groupings of organisms; resemblances among proteins has been used to help reconstruct the history of the evolution and diversification of different forms of life, that is, phylogenetic trees.

Embryological morphology, especially, provided important evidence for common ancestors and a continuous process of branching. Darwin emphasized the differences between the embryonic and adult forms of many animals as well as the very close resemblances of embryos within the same class, arguing that ’ community in embryonic structure reveals community of descent’ (1859: 449). The fact that land-dwelling vertebrates all go through a

gill-arch stage in embryo, for example, is explained by their having descended from fish. Vestigial organs similarly provided strong support for common descent. The presence of the remnants of a pelvis and hind limbs in whales, for example, was explicable through their descent from land mammals.

Finally, the facts of geographic distribution provided particularly important evidence for common ancestors. Darwin emphasized certain features of oceanic islands and their differences from continental islands; oceanic islands have many fewer species, and are typically missing certain types, such as terrestrial mammals and freshwater fishes. Oceanic island species also resemble most of the species from their nearest continent. The inhabitants of the Galapagos archipelago, for example, closely resemble species from the nearby tropical Americas, rather than those from similar temperate climates.

Natural selection. The details of the evidential support for the mechanism of natural selection need to be understood in terms of the structure of natural selection explanations. One remarkable feature of the theory of evolution by natural selection is its explanatory power; it seems that the basic selection framework can be used, when applied with imagination, to account for the emergence, transformation or elimination of *any* trait or population. This flexibility is, in fact, the source of the theory's capacity to underwrite so many hypotheses, and is a primary source of its fruitfulness as a scientific theory.

However, the *proposal* of a selectionist explanation of a trait or evolutionary change is never enough for its scientific acceptance; the hypothesis must be tested. Unfortunately, the traditional emphasis placed on prediction by philosophers of science has contributed to a widespread misperception of the scientific status of these selection hypotheses (Hempel 1965). Under a classical hypothetico-deductive view of theory testing, the theory is used to generate an *outcome* or prediction about the natural system being modelled. If the outcome turns out to hold in nature, the theory is confirmed (see Confirmation theory). In the case of natural selection explanations, however, the outcome - the frequency or nature of the evolved traits - is standardly already known, and the substance of the selection hypothesis involves an account of how the population or trait *got* that way. It may seem, therefore, that all selection explanations could be successfully confirmed as predictions, whether they are true or not.

The logic of testing selection hypotheses was clarified by Darwin: the various empirical claims that appear in any selection explanation - about the existence of variation of reproductive success with the possession of different traits, about the existence and character of environmental stresses, about the inheritance of the relevant variety of traits - must be *independently* confirmed empirically. This independent confirmation of the detailed empirical claims made in selection explanations comprises the chief form of empirical testing for specific evolutionary explanations (Lloyd 1994).

In evolutionary explanations, the abstract framework of selection is filled in with specific details of the particular population, traits and environments at issue; the *empirical content* of any explanation by selection consists of particular claims about particular organisms and their environments. These particular empirical claims are subject to robust evidential testing, independently of any selectionist explanation of which they are a part. There remains, however, a question about the evidential status of the selection framework itself: is it proper to consider the abstract framework well-confirmed, on the basis of its independently confirmed successes in accounting for particular cases of evolution by selection? We tend to regard general theories as well-confirmed if, taken in conjunction with particular facts, they are good at accounting for other particular facts (see §4).

We are now in a position to appreciate the range of evidence relevant to Darwin's theory of natural selection. Important empirical support for natural selection explanations comes from several of the fields that provide evidence for descent with modification. The investigation of homologies, from morphology for example, has provided significant instances of the evolution of special adaptations through natural selection. The bat forelimb - homologous to both the human arm and the canine foreleg - presents an intriguing problem for the theory: how and why did bat ancestors evolve from squirrel-like creatures without wings? The occurrence of random mutation in forelimb form, combined with strong selection on the resulting variation, is used to explain the divergence of bat species from other mammalian species. Similarly, special adaptations to local environments are found to explain a variety of specialized mammalian forelimb forms and functions. The evolution of hundreds of species of bat, all descended from a single ancestral population, is an example of adaptive radiation; specializations in particular prey and particular environments proved advantageous to the survival and reproduction of past bat groups. Even vestigial traits can support the effectiveness of natural selection. The mammalian ancestors of whales, who entered

the water around 55 million years ago, experienced little or no selection pressure to maintain working hindlimbs: mutations and variations in which the hindlimbs were reduced or nonfunctional may have been advantageous, or may have been linked to traits that were advantageous in the new aquatic environments, and subsequently became fixed in the population.

Finally, evolutionary systematics has provided abundant evidence on evolutionary trends and patterns of adaptations, as well as detailing the types of evolutionary transformation that organisms' features undergo, and the patterns of variation within species (Futuyma 1979, ch. 1).

3 Scientifically contested issues

There are currently several areas of controversy within evolutionary biology. One of the most vigorous involves issues of macro-evolution, that is, changes in diversity, the distribution of traits across lineages, extinctions of major taxa, and trends in evolution, such as increase in average size of organisms. The key theoretical questions revolve around the tempo and mode of evolutionary change: when exactly does most evolutionary change occur? Do forms of life evolve mostly gradually, or is evolutionary change concentrated in speciation events? Under what is called the gradualist view, patterns of macro-evolutionary change are explained completely by patterns of gradual selection within species. An important alternative set of mechanisms, advocated since the 1970s by Stephen Jay Gould (1989), Niles Eldredge (1985), Steven Stanley, and other palaeontologists, involves phenomena higher than the species' level, for example, rates of speciation and extinction; under this approach, large-scale events of evolutionary history are explained as consequences of drift of species and species selection (seen as analogous to drift and selection of alleles within populations.)

Another debate about mechanism and the explanation of patterns involves the role of biological development and the ultimate sources of organismal structure. Developmental biologists have been concerned to explore how mutations in genes affect changes in form; some forms are much more likely to arise than others, due to the biochemistry of how organisms grow and change. Selection processes always require the presence of *variation* in traits that matter to the survival and reproduction of genes in an environment. Investigations into which variations are likely and which are even possible can provide information crucial to selection explanations. In addition, the fact that some traits vary along with other ones simply in virtue of how the organism grows makes it vital to incorporate information about the complexities of development into evolutionary explanations.

A very visible and important set of debates has revolved around the levels and units of selection. Generally, disagreement concerns the relative importance of different mechanisms of selection that cause evolutionary change.

Finally, there are robust debates in phylogenetic systematics, some of which concern the detailed evolutionary history of particular species or groups of organisms, and some of which involve the proper role of evolution in phylogenetic systematics. Regarding the latter, Darwin made it clear that he thought that evolution could help systematics by making the classification of life fundamentally a genealogy (Mayr 1982) (see Taxonomy).

4 Philosophical worries - tautology

There is a philosophical concern about modern evolutionary biology which seems to be quite serious: is evolutionary theory based on a tautology? A tautology is a statement that is necessarily true because of the meaning of its terms. Briefly: the theory of natural selection is based on 'the survival of the fittest'; but which organisms are the fittest, according to evolutionary theory? Answer: those that survive. This is the logical truism that is frequently taken to represent the core of evolutionary theory.

Although this objection about tautology has been raised and answered in different ways since the nineteenth century, it continues to cause confusion in each new generation of thinkers facing evolutionary theory. There are two general strategies in answering it. The first is to highlight that, as a matter of fact, the 'fittest' are not defined in terms of survival by evolutionists (Hull 1974). The term 'fitness' has a potentially confusing multiplicity of meanings in evolutionary theory: it can refer to the expected rate of survival and reproduction of a certain type (usually defined in terms of genes); it can also refer to the 'adaptedness' of a certain type of trait to the pressures of its local environment - here, adaptedness is analogous to being well-suited or well-engineered for a specific task. When using this latter meaning of 'fitness', an evolutionist appeals to the suitability of a certain character for

coping with the challenges presented to its owner in the expected environments. (For example, the ’adaptedness’ of being insulated by blubber in arctic environments depends on its effectiveness at maintaining body temperature in mammals compared to other available options, for example, faster metabolism.) Using this substantive notion of the ’fitness’ of an organism possessing a particular trait in a particular environment thus involves no hint of tautology; not only is such a claim substantive, it may be independently testable. Hence, explanations of evolution by natural selection are not tautological.

The second approach to answering the tautology objection is to point out that, strictly speaking, many accepted scientific theories are in fact empirically empty, especially those expressed in mathematical form. A model of a system in Newtonian mechanics is, for example, purely mathematical, as are all predictions arising from the model. This does not prevent the theory from being scientific and empirical, because a proper understanding of the theory entails that the model *represents* some real system which it is used to explain. Similarly, models from mathematical population genetics may show that, as a matter of mathematical deduction, those organisms with higher fitness parameters will necessarily have a higher probability of surviving and contributing to future generations; the related empirical application of the model, however, is not guaranteed to be true. In other words, many mathematically expressed theories - from physics and from natural selection theory - are self-contained or tautologous when taken alone; when used in their scientific context, however, they have precise and testable empirical content (Sober 1993).

The tautology objection can be answered by calling attention to the role of the principle of natural selection - the survival of the fittest - within the rest of the theoretical and explanatory parts of evolutionary theory. When this is done, the objection appears to be based on a misunderstanding of how either the specific theory, or scientific theories generally, really do their work (see Theories, scientific).

5 Philosophical worries - prediction

One of the most common misperceptions of evolutionary theory is that it makes no predictions, concerning, as it does, the past history of life. But being about past events does not prevent a science from being predictive; there are numerous predictions from evolutionary biology which concern the fossil record. For example, whatever will be discovered in the fossil record in the future, mammals will not appear at a date prior to the evolution of bony fishes. Nor will hominids be found to coincide in time with the large dinosaurs. Nor will fossil birds predate the earliest amphibia. Evolutionary theory also underwrites many predictions about genetic findings; closely related species are predicted to share a larger percentage of their basic genetic material than less closely related species and groups. These genetic predictions, made on the basis of evidence preceding the discovery of DNA, have recently gathered abundant empirical confirmation.

There is a distinct concern about evolutionary explanations, which is that they depend so strongly on uncontrollable and, in most cases, unpredictable contingencies - such as environmental changes, chance mutations, or complex interactions among members of a species - that it is impossible for evolutionists to predict the direction that evolutionary processes will take a given population in the future. Evolutionists faced with the question, ‘Which way is humankind evolving?’, admit that evolutionary theory does not enable this type of prediction.

The mathematical models of modern population genetics do allow precise predictions to be made regarding, for example, the future frequencies of specific forms of genes (called ’alleles’) in a population of laboratory fruitflies. These successes are very significant in their support of the efficacy of natural selection, random genetic drift or mutation rates, as causes of evolutionary change. However, population genetics does not presently have the capacity to predict changes over the periods of time involved in major evolutionary events such as speciation, which take place on the order of tens of thousands of years.

More generally (as reviewed in §2) the overemphasis on prediction in understanding scientific evidence has contributed to a failure to understand the evidential relations on the basis of which evolutionary claims are scientifically evaluated.

6 Philosophical worries - design

Design seems to be everywhere in nature; this fact supported the efforts of eighteenth and nineteenth century churchmen, such as William Paley, to encourage piety through the study of nature (see Paley, W. §2). The

existence of order, complexity and adaptedness in living things is still the most common reason given by those who believe in direct supernatural creation of the myriad forms of life on earth. As reviewed in §1, the presentation, development and broad, detailed evidential support of the theory of evolution have provided a scientific and empirically tested alternative to the hypotheses of direct supernatural design. The empirical successes of the modern theory, its compatibility and interdependence with other natural sciences, and its fruitfulness in facilitating scientific investigations into life, have led to its scientific acceptance as an adequate non-supernatural account of the very features of life that were formerly taken to be explicable only by the actions of a supernatural creator (Dawkins 1986) (see God, arguments for the existence of §§4-5; Religion and science §§4-5).

The distinction between proximate and ultimate causes in biological explanations is useful in understanding goal-like states and the appearance of design. *Proximate* causes concern the functions of an organism and its parts, as well as its development. *Ultimate* or evolutionary causes concern why an organism is the way it is. Any biological phenomenon has two independent sets of causes, according to Ernst Mayr, ‘ because organisms have a genetic programme. Proximate causes have to do with the decoding of the programme of a given individual: evolutionary causes have to do with the changes of genetic programmes through time, and with the reasons for these changes’ (1982: 68). Thus, for example, the proximate causes of sexual differences between male and female fruitflies may be hormonal, while the selective advantage of differential utilization of the food niche may be the ultimate cause of these differences. The design of the system is explained through evolution by natural selection over time, while its local functioning is explained through local conditions.

7 Progress and goals

The mechanisms of evolution seem especially mysterious in their capacity to generate what appears to be *progress*. Reviewing the increased cranial capacity of the hominid lines, for instance, it can appear that there was some goal towards which the hominid group was progressing. However, the appearance of ’upward progress’ is, on the modern theory, misleading; there is no natural goal or state of perfection towards which any lineage has evolved (Gould 1989). The series of improvements manifested in any lineage is solely the produce of evolutionary processes operating locally. As Futuyma notes, ’ future conditions cannot affect present survival. The enduring variations may increase the organism’s complexity or behavioural repertoire, or they may decrease it. They may increase the likelihood of survival through subsequent environmental changes, or they may increase the likelihood of subsequent extinction’ (1979: 7).

Evolutionary theory and social science

Ideas from evolutionary theory impinge on the social sciences in two ways. First, there is the research programme of sociobiology, which attempts to demonstrate the impact of biological evolution on important features of human mind and culture. Second, there is the idea that biological evolution provides a suggestive analogy for the processes that drive cultural change. Both research programmes have tended to focus on the idea of natural selection, even though the theory of biological evolution considers processes besides selection. Sociobiology attempts to show that the following conditional helps explain psychological traits just as it applies to traits of morphology and physiology: if a trait varies in a population, makes a difference for the survival and reproduction of individuals, and is influenced by genetic factors, then natural selection will lead the trait to change its frequency in the population. Models of cultural evolution are built on an analogous conditional: if a set of alternative ideas are found in a culture, and people tend to find some of these ideas more attractive than others, then the mix of ideas in the culture will change. Sociobiology and the understanding of cultural change as an evolutionary process are approaches that have a history and both will continue to be explored in the future. Each is a flexible instrument, which may be better suited to some tasks than to others, and may be handled well by some practitioners and poorly by others. As a consequence, neither can be said to be 'verified' and 'falsified' by their track records to date.

1 What is biological evolution?

The term 'evolution' has a misleading etymology. It comes from the Latin *evolvere*, which means to unfold. In the eighteenth century, the term was used to name the process of ontogeny in which a single organism develops from a fertilized egg into an adult. Later, in the aftermath of Darwin's theory, the term itself underwent an evolution, shifting its application from ontogeny to phylogeny (see Darwin, C.). It now no longer describes the development of an individual organism, but applies to the process of 'descent with modification', whereby new species emerge from ancestral forms.

This transposition in subject matter did not leave the meaning of the term intact. It is natural to think that important aspects of the development of an organism are 'preprogrammed'. Although the environment obviously influences the organism's phenotype in many ways, a great deal of the developmental sequence is relatively invariant over environmental changes. Organisms in the same species often share a fixed sequence of developmental stages, each marked by a special constellation of distinctive traits.

Darwin's theory of evolution entirely rejects this view when it is applied to phylogeny. Although organisms may have a preprogrammed ontogeny, species do not have a preordained phylogeny. There is no such thing as the developmental stages through which a species must pass. Rather, the Darwinian idea is that evolution by natural selection is 'opportunistic'; the trajectory of change is an adventitious consequence of the environmental conditions that the species experiences and the variation that the species happens to contain. There is no inherent tendency for species to evolve in the direction of greater complexity, specialization, or body size. Evolution often moves in those directions, but often it does just the reverse.

Contemporary evolutionary theory retains the twin Darwinian ideas of descent with modification and natural selection as an important cause of diversity. The former idea is usually formulated by saying that all living things on earth, both now and in the past, are part of a single genealogical tree. Current species may be closely related to each other or related only distantly, but all are related. The status of the latter idea is the focus of the debate about adaptationism: how important is natural selection as a cause of the similarities and differences we see within and among species?

When biologists apply this two-part theory, they use the term 'evolution' with a restricted and technical meaning. It does not mean mere change; planets change, but this is not evolution in the biologist's sense. And even when the change occurs in the traits of a population of organisms, the term may still fail to apply. If the organisms in one generation are taller than their parents, this may simply reflect a change in the nutrition available. If the population has not changed its genetic composition, this will be change without evolution. Biologists do not restrict the term 'evolution' to genetic changes; traits of morphology, physiology, and behaviour evolve in the strict sense. However, these phenotypic changes must reflect genetic changes, if they are to be genuinely evolutionary.

2 Two approaches

Biology recognizes other possible causes of evolution besides natural selection. Mutation, migration, systems of mating, recombination, and random genetic drift are examples. However, since natural selection is the factor that has been of greatest interest to the social sciences, it is well to explore its logic a bit further.

If natural selection is to produce biological evolution in a population of organisms, there must be variation in fitness and heredity. Let us explore a simple example to see what these twin requirements mean. Consider a population of zebras in which faster running speed evolves. If this is due to natural selection, then the population must contain variation. So let us suppose that some zebras run faster, others slower, and that this makes a difference in the organisms' fitness - their capacity to survive and reproduce. In particular, we may imagine that running speed affects fitness because faster zebras are better able to evade predators than are slower ones. In addition to these facts about fitness, there also must be a process of heredity: offspring tend to resemble their parents in running speed, and this resemblance, at least in part, is due to genetic factors. These assumptions permit the phenotypic trait to evolve in the population; we expect the average running speed of the organisms in the population to increase.

When the concept of natural selection is applied to the subject matter of the social sciences, these two elements are interpreted either literally or metaphorically. The literal application gives rise to the research programme called sociobiology; the metaphorical application leads to the idea that cultural change involves competition among ideas in which the 'best' ideas survive. A standard example of sociobiological explanation concerns the existence of an incest taboo. Human beings seldom reproduce with close genetic relatives. In addition to this regularity in behaviour, there is also the fact that societies often have norms of prohibition. Sociobiologists propose to explain both the behaviour and the taboo by describing the fitness consequences of inbreeding and outbreeding. Reproduction with close relatives increases the chance that the offspring will possess two copies of deleterious recessive genes. As a result, there has been selection for avoiding such matings. The result is not just that human beings now avoid inbreeding, but that they have a genetic inclination to do so. The dual ideas of fitness and heredity are said to apply to incest avoidance in human beings just as literally as they apply to running speed in zebras.

A good example of the metaphorical application of the biological idea of natural selection is the economic theory of the firm (reviewed in Hirshliefer (1977). The problem is to explain why businesses are usually efficient profit maximizers. One hypothesis is that managers are rational and well-informed; they determine which strategies work best and then they adopt them. The theory of the firm offers an alternative explanation. Firms that are efficient stay in business; those that are not, go bankrupt. The economic market induces a selection process in which only the fit survive. Firms do not rationally adjust their behaviour; rather, the market adjusts the composition of the population of firms.

Notice how the concepts of fitness and heredity are interpreted in this theory. The idea is not that people who run efficient businesses live longer or have more children. The fitness of firms has nothing to do with the biology of survival and reproduction. In addition, the reason that firms in later years tend to resemble their former selves (that is, are relatively stable in the strategies they deploy) has nothing to do with genetic transmission. Although sociobiologists often suggest that incest avoidance is 'in the genes', theorists of the firm do not claim that economic behaviour is genetically encoded. The theory of the firm posits a selection process, but one that is related only metaphorically to the process of biological selection (see Sociobiology).

3 The need for a piecemeal assessment

Proponents and critics of sociobiology often treat that subject as a monolithic entity. Proponents defend sociobiology by emphasizing that human beings are the product of evolution; critics argue that human behaviour is enormously flexible and responsive to cultural context - so much so, that the human mind is said to liberate us from the 'tyranny of the genes'.

Although the interest of reaching a general assessment of the promise of sociobiology is undeniable, it is important to consider its merits and demerits on a case by case basis (Kitcher 1985). Perhaps some elements of human behaviour are adequately explained by the theory of natural selection while others are not. Even if sociobiologists

are right about incest avoidance, it is a separate question whether other behavioural regularities can be explained similarly. We should not accept sociobiology because it is sometimes correct; nor should we reject it because it is sometimes mistaken.

Parallel remarks apply to metaphorical applications of the biological concept of natural selection. It is not inevitable that the theory of the firm is correct. But even if it is, the question remains of which other social regularities can be explained within an evolutionary framework. For example, it is often true that unemployment reduces inflation. The usual supply-and-demand explanation of this fact does not advert to different individuals deploying different strategies and, as a result, prospering to different degrees. Rather, the usual approach holds that all individuals are rational or approximately so. All individuals try to pay the lowest price they can. The social regularity is explained by the hypothesis that people are, in the relevant respect, always the same. This is not an explanation in which behavioural variation is sifted and winnowed.

4 The explanation of variation in sociobiology

Well posed problems about the evolution of behaviour concern the explanation of variation. It is all too easy to explain why human beings ‘tend’ to avoid incest by saying that this behaviour maximizes fitness. The word ‘tend’ is vague; how much incest would we have to observe to cast doubt on the evolutionary explanation? A better formulated problem would begin by measuring the amount of inbreeding that occurs in a range of species, our own included. Accounting for this quantitative data gives more structure to the problem.

Although sociobiologists often are interested in explaining features of human behaviour that they believe are cultural universals, they also are interested in explaining behavioural variation among human beings. Perhaps the most familiar context for this type of problem concerns differences between the sexes. Behavioural differences between men and women, they argue, can often be explained by the hypothesis that men and women have evolved in response to different selective pressures. A standard example is their claim that men tend to be more sexually promiscuous than women because selection placed a larger premium on being discriminating about sexual partners in females than it did in males. The claim is not that all men are more promiscuous than all women; rather, selection is said to be an important influence on the behaviour, the result of which is different averages for the two sexes.

Sociobiologists are often criticized for assuming that ‘genetic determinism’ is true - that human behaviour is rigidly controlled by genes and cannot be changed by environmental factors. There are two defects in this general criticism, correct though it may be in some instances. First, even when sociobiologists claim that genetic differences are a cause of the phenotypic variation under study, they are not committed to saying that this is the only cause. For example, even if there is a genetic basis for some behavioural differences between the sexes, this does not exclude the possibility that environmental causes also play a role.

The second defect in the charge of genetic determinism is that some sociobiological explanations of behavioural variation are purely environmental. Consider, for example, Alexander’s 1979) proposed explanation of the kinship system known as the avunculate. In some societies, men provide more care for their sister’s children than for the children of their own wives. Alexander argues that this behaviour will be selectively advantageous when there is considerable female promiscuity. The avunculate maximizes a man’s inclusive fitness if he is more likely to have genes in common with his nephews and nieces than he is with his wife’s children.

The point of interest here is not whether this explanation is empirically correct, but the role it assigns to genetic factors. Alexander is not saying that societies that deploy the avunculate are genetically different from societies that do not. Rather, his idea is that human beings have basically the same genetic endowment, one that leads them to behave in ways that maximize their fitness. A behaviour that maximizes fitness in one circumstance may not do so in another. According to Alexander’s model, the within-species variation in behaviour is explained environmentally, not genetically.

5 The meaning of fitness in evolutionary epistemology

John Stuart Mill defended the value of freedom of thought and expression by describing a ‘marketplace of ideas’ in which ideas compete for acceptance (see Mill, J.S.). Consumers judge which ideas are best, and so the quality of ideas found in the market gradually improves. Evolutionary epistemologists, such as Karl Popper, Donald

Campbell, and David Hull, argue that this idea may be applied fruitfully to the scientific process itself (see Bradie 1994). Scientists are the consumers; they propose theories that compete with each other in an ideational environment. Successful theories persist; unsuccessful theories suffer extinction.

Literal applications of the concept of biological evolution by natural selection not only posit fitness differences among traits, but explain why the traits have the fitness consequences they do. In the mundane example of running speed in zebras, the claim was not just that fast zebras are fitter than slow ones, but that this is so because running speed enhances a zebra's ability to evade predators. It is important not to forget this further element when evolutionary epistemologists propose to use natural selection as a metaphor for scientific change.

It is harmless to say that theories differ in their (cultural) fitness. But what makes for a fitter theory? That is, which properties of a theory bear on its chances of surviving and spreading in the market-place of ideas? There are many possibilities, as the ongoing dispute between internalists and externalists in the history of science attests. An extreme internalist might say that observational support is the only important factor influencing a theory's viability. An extreme externalist might say that ideological palatability is all that matters. In between these extremes are pluralistic theories which say that a variety of factors influence whether a theory will be accepted. The point is that in a model of ideational selection, everything depends on the substantive account of fitness. The model risks vacuity if fitness is left unexplained (see Internalism and externalism in epistemology §4).

In developing a substantive model, the theorist must decide whether the goal is descriptive, or normative, or both. Is the point to describe how scientists actually evaluate theories or how they should do so? These two goals will coincide to the extent that the theorist believes that scientists are rational.

6 Cultural evolution without selection

The concept of natural selection is so striking an ingredient in evolutionary theory that it is easy to forget the theory's other resources. As noted earlier, a fundamental ingredient in current evolutionary theory is the idea of phylogenetic relationship. Current species have common ancestors, and a great deal of work in evolutionary biology is devoted to determining what the family trees are for various taxonomic groups. The detailed working out of ancestry is a quite separate task from the problem of identifying the adaptive significance, if any, of the traits that various species possess.

Social scientists have explored the idea that elements of culture are sometimes related to each other genealogically. For example, historical linguists attempt to determine which languages are closely related to each other and which are related only distantly. This enterprise leads them to postulate unobserved languages, such as proto-Indo European, which are said to be the ancestors of current languages. In similar fashion, philologists study the provenance of manuscripts and try to reconstruct an *Urtext* that lies at the root of a branching tree, the tips of which represent the variants of the manuscript they observe.

There is an important isomorphism between the biologist's problem of phylogenetic inference and the historian's problem of inferring the genealogy of cultural objects. What is observed, in the first instance, are species or artefacts that exist now. From the pattern of similarity and difference they exhibit, one postulates a branching tree, whose internal nodes and root represent species or artefacts that are not observed. The epistemological problem is how to judge this postulated tree in the light of available evidence. What makes one postulated tree more plausible than another? This common methodological problem is, and will continue to be, an arena for mutual influence between biology and the social sciences.

7 Philosophical connections

In addition to the relationships just sketched between evolutionary theory and the social sciences, there is considerable overlap in the philosophical questions pertinent to each.

The issue of reductionism arises in several forms. One involves sociobiology's attempt to 'reduce' certain social and psychological phenomena to biology. A second concerns whether biology and the social sciences are each 'reducible in principle' to physics. A third is occasioned by the fact that the relationship of wholes and parts is an important subject in both sciences; the dispute between methodological holism and individualism arises in both.

A second domain of philosophical overlap concerns the role of teleological concepts. Just as a biologist might say

that the function of the heart is to pump blood, so a social scientist might say that the function of ideology is to preserve existing power relations. It is worth asking what such functional claims mean and what ramifications they have for the aims and methods of the sciences in which they occur.

Finally, both the social sciences and biology deal with systems on which a large number of different causes impinge. This makes especially important the project of understanding how real causes may be disentangled from spurious ones and what it means for one cause to be more important than another.

Examples in ethics

Philosophers often employ examples to illustrate how their favoured principles are to be applied to concrete cases, and sometimes even to show that principles are of no help in decision-making. Examples are also used to convince readers of the existence of moral dilemmas - unresolvable conflicts between moral obligations. But a variety of different philosophical questions concerning the role, status, and nature of examples used in ethics have also been raised. One such question concerns the role that examples should play in our moral experience: should this be a rhetorical, pedagogic role of persuading us to do what is right, as determined by pre-existing principle; or a stronger, logical role of helping to determine what is morally right? Another query relates to moral teaching: is exposure to and reflection on stories, tales, narratives and exemplars sufficient for moral education, or is there a further need for exposure to principles and theories of ethics? Third, in terms of the kinds of examples employed in moral philosophy and reflection, should such examples be culled from great literature or sacred texts? Alternatively, should they be actual case studies drawn from real life, or hypothetical but realistic examples constructed by theorists? Or should they be imaginary, highly improbable cases designed to test our intuitions? A fourth question asks how examples are best identified and described, and to what extent the examples used in ethics are themselves theory-laden or even theory-constituted.

1 A rhetorical or logical role?

There is widespread agreement among moral philosophers that relevant examples play an important role in persuading us to do what is morally appropriate and in encouraging us to try to become morally virtuous agents. The right kind of example, skilfully employed and presented, can bring home the moral point to us in ways that the abstractions of theories, principles, and rules often cannot. Vivid examples frequently possess a motivating power that principles lack.

But according to this familiar view, the standards of moral rightness (or courage, generosity, and so on) are always established antecedently by principle and theory. Examples, while important and necessary, particularly in the early stages of moral education, in bringing the abstractions of theory down to earth, thus remain the handmaiden of principle and theory. Kant's warning in *Grundlegung zur Metaphysik der Sitten (Groundwork of the Metaphysics of Morals)* ([1785] 1903: 409) that cogent examples, while serving to 'make perceptible what the practical law expresses more generally', must nevertheless always be judged by 'their true original, which resides in reason' is a classic expression of this position.

However, some philosophers advocate a stronger role for examples, one in which the examples themselves are held to play a logical role in determining what is morally appropriate. On this latter view, examples function not just as applications of rules or illustrations of principles but rather as challenges for moral judgment to respond to particular situations in a manner which goes beyond mere rule-following. Aristotle's doctrine of practical wisdom or *phronēsis*, which holds that the correct decision 'depends on the particular facts and on perception [of the particular facts]' (*Nicomachean Ethics* 1126b4, 1109b20-3) is the classic representative of this latter view (see Aristotle §23; Virtue ethics §6). The medieval tradition of moral casuistry, particularly as elaborated by Aquinas, according to which individual circumstances may 'touch' or alter cases in important ways, represents a critical historical development of this Aristotelian perspective towards examples (see Casuistry).

2 Are examples enough?

Some philosophers argue that moral principles simply do not exist. According to ethical particularists, moral decisions should always be made case by case, without the false support or illusory guidance of moral principles (see Universalism in ethics §3; Moral realism §5; Logic of ethical discourse). Others hold that moral rules and principles, while not illusory, are unhelpful and often harmful in determining what to do and how to live. Antitheorists in ethics attack the whole idea of a moral 'theory' which seeks to evaluate particular situations by reference to general principles. The intellectual ancestry of particularism and antitheory in ethics is diverse; such views have been imputed variously to Aristotle, Wittgenstein, and postmodernists such as Foucault and Lyotard (see Virtue ethics §6; Wittgensteinian ethics §§2-3; Postmodernism). But the upshot of both views is simply that examples are enough. The best approach to moral education and reflection, for adults as well as for children, is one that emphasizes not impersonal principles and abstract arguments but personal exemplars and concrete cases.

Opponents argue that the worthiness of any alleged moral exemplar or example must always be judged according to antecedently established and defended general norms. Here again, Kant is the classic advocate: 'Every example of… [morality] presented to me must first itself be judged by moral principles in order to decide if it is fit to serve as… a model: it can in no way supply the prime source for the concept of morality' ([1785] 1903: 408). Additionally, defenders of theory hold that a primary goal of moral education must always be critical, autonomous reflection concerning norms. Autonomous moral agents do not assent blindly to others' teachings, but strive continually to make the truths of moral exemplars their own by reflecting critically on the legitimacy and justifiability of these teachings.

3 What kind of examples?

Disagreement also exists concerning what kind of examples to use in ethics. Some prefer literary examples, on the ground that they characterize our moral situation more profoundly and precisely than the less engaging, schematic examples constructed by theorists. On this view, personal experience is, in comparison with fiction, too confined and too parochial. Well-crafted literary examples give readers data that is deeper, sharper, and more precise than much of what occurs in real life. Antitheory tendencies often prevail among strong defenders of literary examples as well, in so far as they are committed to the view that the process of understanding our moral situation is a task not for theory but for nonphilosophical genres.

Others hold that case studies from real life are preferable, for the simple reason that moral theories stand a better chance of guiding moral practices effectively if they draw their data from reality rather than fiction. Additionally, it is often held that such examples are less 'cooked' and have fewer hidden theoretical strings attached to them (see §4). Granted, the theorist's own life experience may well be too confined and too parochial to serve as a satisfactory resource, but examples drawn from, for instance, medical practice, environmental policy, or international relations present theorists with more than ample opportunities. Much recent work in applied and professional ethics is inspired by this desire to bring theory into closer contact with actual practice via real-life examples (see Applied ethics §§2, 6). The concern of many virtue ethicists to articulate a more realistic moral psychology by examining the personalities of real-life moral exemplars represents an analogous development.

A third, more traditional camp claims that hypothetical examples constructed by the theorists themselves are the best way to go, on the ground that a better fit between principle and example is thereby achieved. Theorists here are the creators of their examples, and can embellish them to suit their own purposes. Because they have more control over the examples, a clearer, less *ad hoc* picture of how moral choices are to be made can also supposedly be gained. Within this third category one also finds a wide range of hypothetical example-types, extending from bare, highly schematic accounts at one end to intensely detailed and finely nuanced accounts at the other.

Finally, a fourth kind of example which also has its philosophical defenders is what might be called the imaginary case. This type too is of course hypothetical, but more extremely or fantastically so: it frequently involves counterfactual scenarios quite removed from everyday life. Sometimes one senses a frustrated science fiction writer behind the philosopher who concocts such cases, but when skilfully constructed and presented they can serve to flesh out our moral intuitions in ways that less fantastic stories cannot. The idea is then to transfer these intuitions to relevant (more earthly) cases where our intuitions are confused.

4 How to identify and describe examples

Some authors have also pressed sceptical questions concerning the ways in which specific cases are conceptualized and singled out by moral theorists. Postpositivist philosophers of science are fond of slogans such as 'All facts are theory-laden' (see Observation §§3-4), but it would appear that the theory-ladenness of examples used in ethics is radically deeper. What counts as an important moral problem, and the ways and reasons why it counts, are strongly affected by the theory one advocates or presupposes, as well as the time and place in which one lives. Applied and professional ethicists who work closely with practitioners also run the danger of allowing their perspective to be unduly influenced by the concerns of various interest groups and bodies of professional opinion. When unchecked, the result is not a critical reflection on moral practices but merely a reiteration of them. Given the evident theory-ladenness and conventionalism of many examples in ethics, it has been argued that philosophers who employ examples in ethical discussion need to pay much closer attention to the ways in which their examples are chosen and described. Additionally, stronger justificatory strategies are needed to defend such choices and

descriptions against possible alternative conceptualizations.

5 Concluding remarks

The kinds of question philosophers have raised about examples in ethics are diverse, and the above discussion does not claim to be exhaustive. At the same time, some commonality can be detected within this diversity. Simplifying somewhat, one can say that a unifying theme running through at least parts of §§1, 2 and 4 is an ethical variation on traditional metaphysical and epistemological themes concerning the relationship between universals and particulars (see Nominalism; Universals). Within philosophical discussions of ethics, should we grant pride of place to universals or to particulars? Should moral reflection and theory construction proceed in a 'top-down' application of principle to problem, or in a 'bottom-up' manner which insists that all rules and principles must submit to the jurisdiction of specific examples and not the other way around? (Here too, however, one needs to remember to allow room for adamant 'bottom-dwellers' - particularists and antitheorists who dismiss principles altogether.)

Philosophers as a group are undoubtedly more constitutionally principle-prone and theory-inclined than are novelists, dramatists, story tellers, and others who provide moralists with their richest stores of examples. Nevertheless, when philosophers decide to philosophize about ethics they need to keep in mind that they are ultimately philosophizing not about timeless entities but rather about how agents should live and act - agents, that is, who live in a world not only of space, time, and causality, but of history, politics, culture, and assorted other contingencies as well. The philosopher's natural impulse towards abstraction needs to be continually checked in ethics if we are not to lose sight of our subject matter. At the same time, while ethical theory cannot realistically aspire to the same level of generality as, say, astrophysical theory, the perpetual need to reflect on, understand, and evaluate moral examples eventually necessitates the resources of normative theory.

Existence

Philosophical problems concerning existence fall under two main headings: 'What is existence?' and 'What things exist?'. Although these questions cannot be entirely separated, this entry will concentrate on the first.

The question 'What is existence?' has produced a surprising variety of answers. Some hold that existence is a property that every individual has, others that it is a characteristic that some individuals have but other (for example, imaginary) individuals lack, while proponents of the thesis that 'existence is not a predicate' hold that existence is not a property or characteristic of individuals at all.

Other philosophical issues concerning existence include: disputes about whether there are abstract objects (for example, numbers, universals) as well as concrete ones, immaterial souls as well as bodies, possible objects as well as actual ones, and so on; and questions about which entities (if any) are the fundamental constituents of reality.

1 Objects and existence

To the question 'What is existence?' it is tempting to respond: 'A property that belongs to everything'. However, this answer appears to have paradoxical consequences.

An ancient puzzle, traceable to Parmenides, concerns denials of existence. If existence is a property of everything, one cannot talk about anything that does not exist. But if one cannot talk about what does not exist, how can one truly deny the existence of anything? Yet it is obvious that there are true denials of existence (true negative existential statements): Santa Claus does not exist, nor do Henry VIII's seventh wife or talking tigers.

A second puzzle concerns assertions of existence (positive existential statements). If everything that can be talked about exists, how can a true assertion that something exists be other than trivial? Yet it is obvious that there can be true but non-trivial assertions of existence: 'Egg-laying mammals exist', for example, is not trivial; and 'Homer existed' would be informative if true.

One response to these puzzles consists in holding that as well as objects that exist, there are objects that do not exist. Theories of this type are called 'Meinongian' (see Meinong 1904), after the most famous exponent of such a theory (see Meinong, A.). According to a Meinongian theory, the possibility of true negative existential statements is explained by the fact that Santa Claus, the seventh wife of Henry VIII and so on are objects which can be talked about and can possess various properties (such as driving reindeer and being married), but which lack existence. As for the second puzzle: if some objects are nonexistent, it can clearly be informative to be told, of an object, that it exists.

Such a theory may appear to offer an attractive account of discourse about fiction; one that allows us to take at face value the fact that both 'Pegasus has wings' and 'Pegasus does not exist' appear to be true. However, there are features of this Meinongian theory that many find unacceptable. For example, if we are to use the theory to explain all true negative existential statements, we must follow Meinong in admitting that there are impossible objects such as the round square (since 'The object that is both round and square does not exist' is evidently true). Also, the Meinongian theory implies that Pegasus, although nonexistent, is a horse, yet it is debatable whether the property of being a horse can belong to something nonexistent. Even the fundamental tenet of the theory - that we can distinguish being an object from being an existent object - is open to question. If we admit that Pegasus is an object, a possible subject of discourse and a bearer of properties, does it make sense to add that Pegasus does not exist? If the answer is that existence requires location in space and time, although being an object does not, we may ask why we should accept this distinction.

2 The quantifier account of existence

An influential rival to the Meinongian account holds that the puzzles described in §1 above arise from the mistaken assumption that the term 'exist(s)' attributes a property to individuals. This solution employs an account of existence given by Frege and elaborated by Russell (see Frege, G. §2; Russell, B. §9). The account is associated with the slogan 'existence is not a predicate', a dictum derived from the writings of Kant, who anticipated the Frege-Russell theory in claiming that the ontological argument for God's existence depends on the illegitimate

assumption that existence is a property (see God, arguments for the existence of §§2-3).

According to the Frege-Russell theory, the superficial grammatical form of the sentence ‘Egg-laying mammals exist’ (according to which it appears to attribute a property of existence to egg-laying mammals) is misleading. Its true logical form is revealed by reading it as ‘There are egg-laying mammals’, which can be analysed using logical symbolism as ‘ $(\exists x)x$ is an egg-laying mammal’, where ‘ $\exists x$’ is the existential quantifier (to be read as ‘There is some *x* such that…’). According to this ‘quantifier’ account of existence (or of the word ‘exist(s)’) the grammatical predicate ‘exist(s)’ disappears when the sentence is subjected to logical analysis, being replaced by the existential quantifier. As for ‘Talking tigers do not exist’, this is to be treated as equivalent to ‘There are no talking tigers’, which can be analysed as ‘It is not the case that: $(\exists x)x$ is a talking tiger’. Frege and Russell combined this quantifier account of existence with a claim to the effect that although ‘exist(s)’ is not a first-order predicate (a predicate of individuals), it is a higher-order predicate: a predicate of properties. For example, although in ‘Egg-laying mammals exist’ the word ‘exist’ does not ascribe the property of existence to egg-laying mammals, it does ascribe a property - that of being instantiated (‘having an instance’) - to the property of being an egg-laying mammal.

Using his celebrated theory of descriptions, Russell (1918) argued that the quantifier account can be extended to existential sentences involving definite descriptions and proper names, thus providing an ingenious general solution to the puzzles described above (see Descriptions). According to Russell, ‘Henry VIII’s seventh wife does not exist’ and ‘Santa Claus does not exist’ should be construed not as saying, of certain objects, that they lack existence, but rather as saying that certain properties (for example, being a seventh wife of Henry VIII or being a unique white-bearded, reindeer-driving, gift-delivering inhabitant of the North Pole) are not instantiated; that nothing has these properties. Similarly, ‘God does not exist’ is to be interpreted as the claim that a certain property - perhaps that of being a uniquely powerful, wise and benevolent creator of the universe - is not possessed by anything. Finally, if, following Russell, we treat the proper name ‘Homer’ as equivalent to the description ‘the author of the *Iliad* and the *Odyssey*’, we can construe the assertion that Homer existed as the claim that one person wrote both of these poems, an item of information that would be far from trivial.

The quantifier account is widely accepted as an analysis of general existential statements. However, many philosophers have been reluctant to follow Russell in holding that all meaningful existential statements are to be analysed in terms of the existential quantifier. (A notable exception is Quine (1953).) One difficulty is that there appear to be meaningful statements asserting the existence of particular things that resist the quantifier treatment. Even if we accept Russell’s (controversial) analysis of definite descriptions, and accept his descriptive analysis of proper names such as ‘Santa Claus’ and ‘God’, there are powerful reasons for thinking that most proper names are not equivalent to descriptions (see Proper names §§1-3). Hence it is doubtful whether ‘Bertrand Russell existed’ is equivalent to any claim that some set of properties is or was instantiated. Even more recalcitrant are existential statements involving demonstratives, such as ‘This exists’ or ‘That elephant exists’. Unless we say, implausibly, that all such sentences are false or meaningless, we appear to be committed to the conclusion that there are, after all, some true sentences in which ‘exist(s)’ ascribes a property of existence to particular objects. Further, it has been argued that some statements saying that things have existed, will exist, or might not have existed cannot be given a satisfactory analysis without invoking a property of existence.

However, if existence is a genuine property, an account must be given of the relation between this property and the existential quantifier, since it is undeniable that some general existential sentences are closely related to, if not equivalent to, existential quantifications. Moreover, if ‘exist(s)’ can express a property of individuals, does it play this role in any of the negative and positive existential statements discussed in §1? If so, how - assuming that the Meinongian account is rejected - are the puzzles to be solved? And what, if anything, can be said about the alleged property of existence beyond the claim that it belongs to everything? There is at present no consensus about these issues.

Existentialism

The term ‘existentialism’ is sometimes reserved for the works of Jean-Paul Sartre, who used it to refer to his own philosophy in the 1940s. But it is more often used as a general name for a number of thinkers in the nineteenth and twentieth centuries who made the concrete individual central to their thought. Existentialism in this broader sense arose as a backlash against philosophical and scientific systems that treat all particulars, including humans, as members of a genus or instances of universal laws. It claims that our own existence as unique individuals in concrete situations cannot be grasped adequately in such theories, and that systems of this sort conceal from us the highly personal task of trying to achieve self-fulfilment in our lives. Existentialists therefore start out with a detailed description of the self as an ‘existing individual’, understood as an agent involved in a specific social and historical world. One of their chief aims is to understand how the individual can achieve the richest and most fulfilling life in the modern world.

Existentialists hold widely differing views about human existence, but there are a number of recurring themes in their writings. First, existentialists hold that humans have no pregiven purpose or essence laid out for them by God or by nature; it is up to each one of us to decide who and what we are through our own actions. This is the point of Sartre’s definition of existentialism as the view that, for humans, ‘existence precedes essence’. What this means is that we first simply exist *- find ourselves born into a world not of our own choosing - and it is then up to each of us to define our own identity or essential characteristics in the course of what we do in living out our lives. Thus, our essence (our set of defining traits) is chosen, not given.*

Second, existentialists hold that people decide their own fates and are responsible for what they make of their lives. Humans have free will in the sense that, no matter what social and biological factors influence their decisions, they can reflect on those conditions, decide what they mean, and then make their own choices as to how to handle those factors in acting in the world. Because we are self-creating or self-fashioning beings in this sense, we have full responsibility for what we make of our lives.

Finally, existentialists are concerned with identifying the most authentic and fulfilling way of life possible for individuals. In their view, most of us tend to conform to the ways of living of the ‘herd’: we feel we are doing well if we do what ‘one’ does in familiar social situations. In this respect, our lives are said to be ‘inauthentic’, not really our own. To become authentic, according to this view, an individual must take over their own existence with clarity and intensity. Such a transformation is made possible by such profound emotional experiences as anxiety or the experience of existential guilt. When we face up to what is revealed in such experiences, existentialists claim, we will have a clearer grasp of what is at stake in life, and we will be able to become more committed and integrated individuals.

1 Historical development

Although such earlier thinkers as Augustine, Montaigne, Shakespeare and Pascal have been called existentialists, the term should be reserved for a loosely connected group of thinkers in recent times who were responding to certain views that became widespread in the nineteenth century. These views include, first, the scientific picture of reality as a meaningless, value-free collection of material objects in causal interactions, and second, the modern sense of society as an artificial construct that is inevitably in conflict with the aspirations of the individual. German Idealism had attempted to counteract the implications of these new ideas, but idealism had collapsed by the 1840s, and the result was a growing feeling that the individual is ultimately alone and unsupported in a cold and meaningless universe (see Idealism).

Existentialism appeared in the nineteenth century alongside romanticism, but it was different from romanticism in important respects. For one thing, where romanticism tried to evoke a sense of the individual’s participation in the larger context of nature, the first great existentialist, Søren Kierkegaard, held that humans are at the most basic level solitary, ‘existing individuals’ with no real connections to anything in this world. Instead of suggesting that we are at home in this world, Kierkegaard tried to intensify the individual’s feeling of anxiety and despair in order to bring about a ‘leap of faith’ that would bring the person into a defining relationship to the God-man (Christ).

The next figure usually included in the pantheon of existentialists, Friedrich Nietzsche, began from the assumption

that the development of science and critical thinking in Western history has led to the result that people have lost the ability to believe in a transcendent basis for values and belief. When Nietzsche said that ‘God is dead’, he meant that all the things people previously thought of as absolutes - the cosmic order, Platonic Forms, divine will, Reason, History - have been shown to be human constructions, with no ultimate authority in telling us how to live our lives. In the face of the growing ‘nihilism’ that results from the death of God, Nietzsche tried to formulate a vision of a healthy form of life people can achieve once they have given up all belief in absolutes (see Nihilism).

The translation of Kierkegaard’s works and the discovery of Nietzsche’s writings had an immense impact on German thought after the First World War. The psychiatrist and philosopher, Karl Jaspers, drew on these two figures to develop what he called a ‘philosophy of existence’. Martin Heidegger, influenced by Kierkegaard as well as by the movement called ‘philosophy of life’ (then associated with the names of Nietzsche, Wilhelm Dilthey and Henri Bergson), began his major work, *Being and Time* (1927), with an ‘existential analytic’ aimed at describing life from the standpoint of concrete, everyday being-in-the-world (see Lebensphilosophie). Heidegger’s thought was also influenced by Edmund Husserl’s phenomenology, an approach to philosophy that emphasizes description of our experience as it is prior to reflection and theorizing (see Phenomenological movement).

Working independently in France, Gabriel Marcel was building on Bergson’s philosophy to develop an alternative to the dominant idealist philosophy taught in the universities. Basing his reflections on his own experience of life, Marcel claimed that a human being must be understood as an embodied existence bound up with a concrete situation. Because the body and the situation can never be completely comprehended by the intellect, Marcel sees them as part of what he calls the ‘mystery’. Maurice Merleau-Ponty took over Marcel’s notion of embodied being-in-a-situation as basic for his own existential phenomenology. Jean-Paul Sartre also drew on Marcel’s thought, but he was especially influenced by the thought of Husserl and Heidegger. It seems that the term ‘existentialism’ was first used by critics of Sartre, but it came to be accepted in the 1940s by Sartre and Simone de Beauvoir as they replied to their critics. Merleau-Ponty and Albert Camus were initially associated with the movement called existentialism during its heyday after the Second World War, but both eventually rejected the term as they came to distance themselves from Sartre due to political differences.

There have been important developments outside Germany and France. The Spanish philosopher, José Ortega y Gasset, influenced by Dilthey’s philosophy of life, developed a number of ideas that closely parallel those of Heidegger and other existentialist thinkers. The novels and short stories of the Russian writer, Fëdor Dostoevskii, were influential not only for Russian existentialists like Nikolai Berdiaev, but for Heidegger, Sartre and Camus as well. Existentialism has also had a profound impact on other fields. The movement of existential theology remains influential today (see Existentialist theology), and existential psychoanalysis (especially Ludwig Binswanger, Medard Boss and Rollo May) continues to be of interest in psychotherapy. Though existentialism is no longer a central movement in philosophy, many of its principal exponents continue to be important in current philosophical discussions.

2 The human condition

Existentialists start out from the assumption that it is no longer possible to believe that there is some transcendent justification or underlying ground for our existence. If God is dead, then we find ourselves ‘abandoned’, ‘forlorn’, ‘thrown’ into a world, with no pregiven direction or legitimation. Though we seek some overarching meaning and purpose for our lives, we have to face the fact that there is no ‘proper function of humans’ or ‘plan in God’s mind’ that tells us the right way to be human.

This picture of our predicament leads to a particular view of human existence that is accepted by many existentialists. In contrast to traditional theories, which think of a human as a thing or object of some sort (whether a mind or a body or some combination of the two), existentialists characterize human existence as involving a deep tension or conflict between two different aspects of our being. On the one hand, we are organisms among other living beings, creatures with specific needs and drives, who operate at the level of sensation and desire in dealing with the present. At this level, we are not much different from other animals. On the other hand, there is a crucial respect in which we differ from other organisms. One way to describe this difference is to say that, because we are capable of self-awareness, we are able to reflect on our own desires and evaluate ourselves in terms of some larger vision of what our lives are adding up to. In this sense we transcend our own being as mere things. What is

characteristic of our being as humans is that we *care* about the kinds of beings we are, and we therefore take a stand on our basic desires. According to the existentialists, humans are unique among entities in that they form second-order desires about their first-order desires, and they therefore have aspirations that go beyond the immediacy of their sensual lives.

Heidegger and Sartre try to capture this reflexive dimension of human existence by saying that what is unique about humans is that their own being is ‘in question’ or ‘at issue’ for them. What kind of person I am matters to me, and because I am concerned about what I am and will be, I take some concrete *stand* on my life by assuming roles and developing a specific character through my actions. But this means that my existence is characterized by a fundamental tension or clash between my immediate sensations and desires on the one hand, and my long-range aims and projects on the other. As Sartre puts it, a ‘rift’ or a ‘gap’ - a ‘nothingness’ - is introduced into the fullness of being in the universe by human existence. Because consciousness makes us more than what we are as creatures with immediate sensations and desires, Sartre says that human reality ‘is not what it is and is what it is not’.

The conception of human existence as a tension also appears in Kierkegaard’s description of the self. For Kierkegaard, humans are both finite and infinite, temporal and eternal, contingent and free. What defines our identity as selves is the concrete way we relate ourselves to this tension. In a similar way, Nietzsche holds that we are both creatures and creators, and we have to embrace both these dimensions of ourselves in order to be fully human. Heidegger and Sartre refer to the two aspects of the self as ‘facticity’ (our mere givenness) and ‘transcendence’ (our ability to surpass our givenness through our interpretations and aspirations). In their view, life is a continuous tension between these elements, a tension resolved only in death. Finally, Jaspers seems to have a similar conception of humans in mind when he points out the polarity between our being as an empirical consciousness-as-such and our desire to grasp the general and realize our freedom as *Existenz*.

If we regard the self as a tension or struggle, it is natural to think of human existence not as a thing or object of some sort, but as an unfolding event or happening - the story of how the tension is dealt with. What defines my existence, according to this view, is not some set of properties that remain the same through time, but the ‘event of becoming’ through which I carry out the struggle to resolve the tension that defines my condition in the world. As an ongoing happening, I *am* what I make of myself throughout the course of my life as a whole. In Ortega’s words, a human ‘does not have a nature, but rather a history’ (see Ortega Y Gasset, J.). What defines my existence as an individual is the ongoing story of what I accomplish throughout my life.

To think of a human as an unfolding story suggests that human existence has a specific sort of temporal structure. We are not like rocks and cauliflowers which continue to exist through an endless sequence of ‘nows’. Instead, human temporality has a kind of cumulativeness and future-directedness that is different from the enduring presence of physical things. First, our existence is directed toward the future to the extent that we are striving to realize something for our lives. Heidegger calls this element of ‘futurity’ our ‘being-*towards*-death,’ understood as a movement toward realizing our own being by achieving certain things throughout our active lives. Second, the past shows up for us as something retained and carried forward for the purposes of our future. Depending on our projects at any given time, our past actions show up for us as assets or as liabilities in relation to what we are doing. Finally, our present appears as a point of intersection between our future projects and our past accomplishments. Because we are time-binding beings whose lives always reach out into the future and hold on to the past, we can never achieve the kind of direct presence of self to self that Descartes thought he had found in the *Cogito* (‘I think’).

To say that human temporality is cumulative is to say that everything we do is contributing to creating our ‘being’ as a totality. In this sense, we *are* what we *do* in living out our lives: we define our own identity through the choices we make in dealing with the world. Because there is no fixed essential nature which we have in advance, our ‘essence’ as individuals is defined and realized through our concrete existence in the world. Whatever capacities and traits I am born with, it is up to me to take them over and make something of them in what I do. Thus, whether aware of it or not, I am creating my own identity in my actions.

3 Being-in-the-world

Existentialists are deeply suspicious of the high-level, abstract theorizing about humans found in traditional philosophy and in the sciences. In their view, the concern with subsuming all particulars under concepts and

building systems tends to conceal crucial features of our lives as individuals. For this reason, existentialists generally start out from a description of ourselves as agents in everyday contexts, prior to reflection and theorizing. These descriptions reveal that it is part of our 'facticity' that we are generally caught up in the midst of things, involved with others in trying to accomplish specific goals, and affected by moods and commitments that influence our perception and thoughts. Furthermore, we are embodied beings who encounter the world only from the standpoint of a particular bodily orientation that gives us a set on things: 'I am my body' Marcel wrote, and this theme of embodiment became central to the thought of Beauvoir and Merleau-Ponty. We are also bound up with contexts of equipment in practical situations where we are trying to accomplish certain goals. Finally, as social beings, we always find ourselves embedded in a particular cultural and historical milieu that conditions our outlook and determines our basic orientation toward the world. To say that we are 'factical' beings is to say that we are always 'being-in-a-situation', where our being as selves is inseparable from a shared, meaningful life-world.

If we are always embedded in a situation, then all inquiry must start out from an 'insider's perspective' on things, that is, from a description of the world *as it appears to us* - to beings who are participants in our forms of life, with our unique sort of bodily set, feelings and modes of perception. We have no choice but to begin from where we stand in the thick of our actual lives, with our local attachments and particular cares and concerns. But this means that there is no way to achieve the sort of global 'God's-eye view' on ourselves and our world philosophers have sought ever since Plato. Existentialists are critical of the philosophical ideal of achieving a totally detached, disinterested, disengaged 'view from nowhere' that will provide us with completely objective knowledge. The attempt to step back from our ordinary concerns in order to achieve a totally detached and dispassionate standpoint - the stance Marcel calls 'desertion' and Merleau-Ponty calls 'high-altitude thinking' - will always give us a distorted view of the world, because it bleaches out our normal sense of the significance and worth of the things we encounter around us. In order to be able to gain an insight into the way reality presents itself to us at the most basic level, then, we need to start from a description of what Heidegger calls our 'average everydayness', our ordinary, familiar ways of being absorbed in practical affairs.

The idea that our being-in-a-situation or being-in-the-world is fundamental and inescapable gives the existentialists a way of criticizing the idea, central to philosophy since Descartes, that we are at the most basic level *minds* receiving sensory inputs and processing information. Sartre, for example, rejects the idea that the self can be thought of as a 'thinking substance' or self-encapsulated 'field of consciousness' distinct from the world. In my pre-reflective activities, Sartre says, I encounter myself not as a bundle of beliefs and desires in a mental container, but as being 'out there' *with* the things I am concerned about. When I am chasing a bus, I encounter my *self* as a 'running-toward-the-bus'. My being is found not in my head, but with the bus. Sartre thinks that this follows from Husserl's view that consciousness is always 'intentional,' always directed *towards* entities in the world (see Intentionality). If Husserl is right, according to Sartre, then the 'I' is not an object, not a 'something', but is instead sheer intentional activity directed towards things in the world. The totality of my intentional acts defines me; there is no residue of 'substantial thinghood' distinct from my acts.

The existentialist conception of our irreducible being-in-a-situation calls into question some of the dualisms that have dominated so much of Western thought. First, existentialists deny the romantic distinction between an outer self - what we *do* in the world - and an inner, 'true' self that embodies our genuine nature. If we just *are* what we *do*, as existentialists contend, then there is no basis for positing a substantive 'real me' distinct from the parts I play and the things I do. Second, the account of the primacy of being-in-the-world tends to undermine the traditional subject-object model of our epistemological situation. Existentialists suggest that the assumption that humans are, at the most basic level, subjects of experience trying to formulate beliefs about objects on the basis of their inner representations, distorts our situation. If it is true that we are initially and most basically already out there with things in the world, then there must be something wrong with traditional epistemological puzzles about how a knowing subject can 'transcend' its veil of ideas to gain knowledge of objects in the external world. Finally, the existentialist picture of our basic situation as always bound up with a practical life-world seems to raise questions about the traditional fact-value distinction. Existentialists hold that we always encounter the everyday life-world as a context of equipment bound up with our aims as agents in the world. If the things we encounter are initially and most basically functional entities tied up with our purposive activities, however, then it is an illusion to think that what is given 'at first' is a collection of brute objects we subsequently invest with subjective values.

In our everyday lives, fact and value are inseparable.

In general, existentialists hold that traditional dualisms arise only when we try to adopt a cool, detached, theoretical stance towards things. But since such a stance is derivative from and parasitic on a more basic way of being in which we are inseparably bound up with things in practical contexts, it cannot be regarded as providing us with a privileged insight into the way things really are.

4 Freedom and responsibility

As being-in-the-world, we are already engaged in a shared life-world that gives us a prior sense of what is possible, and we find ourselves with choices in our past that carry weight in determining how we can act in the future. This is our 'facticity', and it makes up what is just 'given' in our lives. However, existentialists regard facticity as only one aspect of human existence, for they hold that humans always have the ability to transcend their given situation by taking a stand on their own lives. As 'transcendence' we are always taking over our situations and making something of them through our choices. This ability to transcend our facticity means that we have free will. Our choices are free in the sense that (1) no outside factors determine our will, (2) in any particular case we could have acted otherwise than we did, and (3) we are therefore responsible for our choices in a way that justifies moral praise and blame (see Free will). (Nietzsche is inclined to reject the third sense because of its role in imposing feelings of guilt on people, but in other respects he seems to be committed to believing in human freedom.)

The existentialist belief in human freedom is based on a phenomenological description of our everyday lives. In confronting situations where I must make a choice, I find myself facing an open range of possible courses of action where nothing compels me to choose one course of action over the others. Even in cases where I am not aware of making choices, a moment's reflection shows that I am in fact deciding my own life. Suppose that I show up for work faithfully each day, and I believe that I am compelled to do this because I need to make money to support my family. Does this mean that I am forced to do what I do? An existentialist like Sartre would say that it is self-deception to think I am *compelled* to be a conscientious worker, for I *could* always walk away from it all and join a monastery or turn to a life of crime. If I am choosing to let considerations of duty or money be deciding factors for me in this way, then this is my choice. What this suggests is that even in my habitual and seemingly 'automatic' actions I am actually *assuming* a particular identity for myself through my own free choices, and am therefore responsible for what I do.

Sartre tries to capture this idea by saying that humans are 'condemned to be free'. Because our being is 'in question' for us, we are always taking it over and giving it some concrete shape through our actions. And this means that, whether we are aware of it or not, in continuing to act in familiar ways we are constantly renewing our decisions at every moment, for we could always change our ways of living through some radical self-transformation. Moreover, since all criteria or standards for evaluating our actions are also freely chosen, in our actions we are also deciding what sorts of reasons are going to guide our actions. With no higher tribunal for evaluating reasons for acting, we are entirely responsible for what we do: we have 'no excuses behind us nor justifications before us'.

Existentialists generally hold that we are not only responsible for the direction our own lives take, but also for the way the world around us appears. This idea has its roots in Kant's view that the reality we experience is partly shaped by the constituting activity of our own minds, though existentialists differ from Kant in holding that our construction of reality depends on our own choices (see Kant, I. §5). Kierkegaard, for example, contends that one's sense of reality is determined by the 'sphere of existence' in which one lives, so that the person who lives the life of a pleasure-loving aesthete will experience a world that is quite different from that of the duty-bound follower of the ethical. Similarly, Nietzsche holds that reality is accessible to us only through some 'perspective' or other, that there is no way to get in touch with reality as it is in itself, independent of any point of view or framework of interpretation.

Sartre works out an especially strong version of this Kantian outlook by developing the theory of constitution in Husserl's phenomenology. Husserl held that the world we experience is constituted through the meaning-giving activity of consciousness. Sartre takes this account of constitution to mean that, because I shape the world around me through my meaning-giving activity, I am ultimately responsible for the way the world presents itself to me in

my experience. Thus if I have had some painful experiences as a child, it is up to me to decide what these mean to me. I can use them as an excuse for going through life feeling cheated, or regard them as challenges that will make me stronger. Sartre's point is not that there are no constraints on the ways I interpret my situation, but that constraints and obstacles gain their meaning from me, and since there are indefinitely many possible meanings any situation can have, there is no way to identify any supposedly 'hard' facts that could be said to compel me to see things one way rather than another. But this means, according to Sartre, that in choosing my interpretation of myself, I simultaneously choose the world. It is our own freely chosen projects that determine how reality is to be carved up and how things are to count. Sartre even goes so far as to say that, if a war breaks out around me, then I am responsible for that war, because it is up to me to decide what the war is going to mean to me in my life.

Other existentialists have tried to formulate a more tempered conception of freedom. Kierkegaard argues that, because being human involves both necessity and possibility, the extreme sort of 'anything-goes' freedom (such as that later envisaged by Sartre) would lead to the 'despair of lack of necessity'. Both Heidegger and Merleau-Ponty work towards a notion of 'situated freedom' according to which choice is always embedded in and dependent upon the meaningful choices disclosed by a specific social and historical situation. Beauvoir tries to show how institutions and social practices can cut off the choices open to women and oppressed groups. Finally, Nietzsche calls attention to the way biological and historical factors operate 'behind our backs,' influencing our decisions without our awareness. But even when such limitations are recognized, the belief that we can rise above our situations to be 'creators' remains fundamental to existentialist thought.

5 Everyday existence, anxiety and guilt

Though existentialists agree that people are free to choose their own fates, they also hold that most people are quite unaware of their freedom. This obliviousness results not from ignorance or oversight, but from the fact that we usually try to avoid facing up to our responsibility for our lives. For the most part we are 'fleeing' from ourselves, throwing ourselves into mundane concerns and drifting into standardized public ways of acting. Existentialists are generally quite critical of everyday social existence. As they see it, there is a strong temptation to let ourselves get swallowed up by the 'public', the 'they', the 'herd' or the 'masses'. We try to do what 'one does' in familiar situations, and we assume that our lives are justified so long as we are following the norms and conventions laid out in our social context. In throwing ourselves into the kinds of busy-ness characteristic of contemporary society, we become more and more effective at finding means to achieving socially accepted ends, but at the same time we lose the ability to understand what is at stake in existing. Life then becomes a disjointed series of episodes with no real coherence or direction, and we end up dispersed and distracted, lacking any basis for meaningful action.

Existentialists give similar accounts of how social existence undermines our ability to realize ourselves as individuals. Kierkegaard describes the way that being a well adjusted member of 'the public' levels everything down to the lowest common denominator, with the result that nothing can really *count* or *matter* to people anymore. Similarly, Nietzsche describes the way that our being as 'herd' animals domesticates us and deadens our creativity, and Heidegger points out the 'tranquilization' and 'alienation from ourselves' that results from our absorption in the familiar social world. Sartre presents an especially harsh picture of social relations. Since, in his view, people can only see each other as objects and not as free beings, the Look of the Other always objectifies me and pressures me into thinking I am just a brute thing. As each individual struggles to affirm their being as a free 'transcendence' against the objectifying Look of others, the result is inevitable conflict: in the words of a character in one of Sartre's plays, 'Hell is the others'.

But many existentialists also see a positive side to social life. Though Heidegger criticizes the temptation to self-loss in our participation in the 'they', he also holds that all our possible ways of interpreting ourselves ultimately come from the social context in which we find ourselves. For this reason, becoming authentic is not a matter of escaping society, but of embracing our social existence in the right way. Marcel's attitude toward social existence shows how different he is from Sartre. He criticizes the 'technocratic attitude' of mass society not because it leads to conformism, but because it breeds an 'atomic individualism' that robs us of our deep sense of connection and obligation to others. And Jaspers and Buber both emphasize the importance of 'I-Thou' relations in realizing a full and meaningful life.

Although existentialists differ in their assessment of social existence, they agree in thinking that our ordinary, day-to-day existence is shot through with concealment and self-deception. What can free us from this distorted

sense of things is not rational reflection, but a profound affective experience. This emphasis on the role of emotions or moods in giving us access to the truth about ourselves is one of the most characteristic features of existentialist thought. Kierkegaard and Heidegger, for example, focus on the disclosive role of anxiety in leading us to confront the fact that we exist as finite beings who must decide the content of our own lives. Jaspers' concept of 'limit-situations' refers to situations in which our ordinary ways of handling our lives 'founder' as we encounter certain inescapable 'antinomies' of life. For Sartre, the feeling of *nausea* shows us that it is up to us to impart a meaning to things, and *anguish* reveals our 'terrible freedom' to decide our own fates. Finally, Marcel refers to the experience of *mystery* in which we encounter that which defies our ability to gain intellectual mastery through our problem-solving skills.

Some existentialists also talk about an experience of the absurd that can come over us in our rationalistic age. Sartre claims that there are no ultimate grounds that validate our choices, so that any fundamental project we adopt must be absurd in the sense that it is ultimately unjustified. Camus' conception of the absurd is perhaps the best known of all, though it is not really representative of existentialist thought. In *The Myth of Sisyphus* (1942a), he describes the feeling of futility we can experience when we become aware of the repetitiveness and pointlessness of our everyday routines and rituals. For Camus, this feeling of the absurdity of existence, a feeling in which suicide begins to seem like a real possibility, is the most fundamental experience philosophy must confront.

Finally, many existentialists point to the experience of guilt as providing an insight into our own being. Existential guilt refers to something broader than the feeling we sometimes have when we have done something wrong. In its broadest significance, existential guilt refers to the fact that there is no pre-given legitimation or justification for our existence. Though we are creatures who feel the need for some 'reason for existing', we find ourselves thrown into a world where there is no higher court of appeals that could validate our lives. We are ultimately answerable only to ourselves. In a somewhat narrower sense, existential guilt can refer to the fact that, because we are always engaged in acting in concrete situations, we are implicated in whatever happens in the world, and so we always have 'dirty hands'.

6 Authenticity

Experiences like anxiety and existential guilt are important, according to existentialists, because they reveal basic truths about our own condition as humans. Everyday life is characterized by 'inauthenticity', and in our ordinary busy-ness and social conformism we are refusing to take responsibility for our own lives. In throwing ourselves into socially approved activities and roles, we disown ourselves and spin a web of self-deception in trying to avoid facing up to the truth about what we are. This picture of inauthentic existence is contrasted with a vision of a way of living that does not slide into self-loss and self-deception. Such a life is (using the term found in Heidegger and Sartre) 'authentic'. Authenticity suggests the idea of being true to yourself - of owning up to who you really are. However, it is important to see that authenticity has nothing to do with the romantic ideal of getting in touch with an 'inner self' that contains one's true nature, for existentialists hold that we have no pregiven 'nature' or 'essence' distinct from what we do in the world.

If authenticity is not a matter of being true to some core of traits definitive of the 'real me', what is it? For most existentialists, becoming authentic is first of all a matter of lucidly grasping the seriousness of your own existence as an individual - the raw fact of the 'I exist' - and facing up to the task of making something of your own life. Kierkegaard, for example, holds that the only way to succeed in becoming a 'self' (understood as an 'existing individual') is by living in such a way that you have 'infinite passion' in your life. This kind of intensity is possible, he thinks, only through a total, life-defining commitment to something that gives your life an ultimate content and meaning. Nietzsche is also concerned with getting us to take hold of our own lives in a more intense and clear-sighted way. To free people from the attempt to find some overarching meaning for their lives, he proposes the idea of eternal recurrence: the idea that everything that happens in your life has happened before in exactly the same way, and will happen again and again, an endless number of times. If we accept this, Nietzsche suggests, we will be able to embrace our lives as they are, on their own terms, without regrets or dreams about how things could be different. Heidegger suggests that, in the experience of anxiety, one confronts one's own 'naked' existence as 'individualized, pure and thrown'. As we become aware of our 'being-towards-death' in this experience, we will grasp the weightiness of our own finite lives, and we will then be able to seize on our own existence with integrity, steadiness and self-constancy.

Many existentialists agree that owning up to one's own existence requires a defining commitment that gives one's life a focus and sense of direction. For Kierkegaard, a religious thinker, self-fulfilment is possible only for the 'knight of faith', the person who has a world-defining relation to a particular being which has infinite importance (the eternal being who has existed in time, the God-man). For Heidegger, authenticity requires 'resoluteness', a commitment to some specific range of possibilities opened up by one's historical 'heritage'. The fact that the ideal of commitment or engagement appears in such widely different existentialist works raises a question about the distinction, first made by Sartre, between 'religious' and 'atheist' existentialists. Kierkegaard, Marcel and Jaspers are often grouped together as religious existentialists, yet there are profound differences in their views of the nature of religious commitment. Where Kierkegaard emphasizes the importance of relating oneself to a concrete particular, Marcel and Jaspers speak of a relation to the 'mystery' or to 'transcendence' (respectively). At the same time, so-called 'atheist' existentialists like Heidegger and Sartre tend to agree with Kierkegaard's view that being 'engaged' or having a 'fundamental project' is necessary to achieving a focused, intense, coherent life. The distinction between atheist and religious existentialists becomes harder to maintain when we realize that what is important for religious thinkers is not so much the factual properties of the object of commitment as the inner condition of faith of the committed individual. Thus, Kierkegaard says that what is crucial to faith is not the 'objective truth' about what one believes, but rather the intensity of one's commitment (the 'subjective truth').

The idea that intensity and commitment are central to being authentic is shared by all types of existentialists. Another characteristic attributed to an authentic life by most existentialists is a lucid awareness of one's own responsibility for one's choices in shaping one's life. For Sartre, authenticity involves the awareness that, because we are always free to transform our lives through our decisions, if we maintain a particular identity through time, this is because we are choosing that identity at each moment. Similarly, Kierkegaard and Heidegger talk about the need to sustain our identity at each moment through a 'repetition' of our choice of who we are. In recognizing our freedom to determine our own lives, we also come to accept our responsibility for who we are.

The notion of authenticity is supposed to give us a picture of the most fulfilling life possible for us after the 'death of God'. It calls on us to assume our own identities by embracing our lives and making something of them in our own way. It presupposes lucidity, honesty, courage, intensity, openness to the realities of one's situation and a firm awareness of one's own responsibility for one's life. But it would be wrong to think of authenticity as an *ethical* ideal as this is normally interpreted. First, becoming authentic does not imply that one adopts any particular moral code or follows any particular path: an authentic individual might be a liberal or a conservative, a duty-bound citizen or a wild-eyed revolutionary. In this respect, authenticity pertains not to *what* specific kinds of things you do, but *how* you live - it is a matter of the style of your life rather than of its concrete content. Second, in formulating their different conceptions of authenticity, many existentialists describe the ideal of authenticity in terms that suggest that it can be opposed to ethics as ordinarily understood. Kierkegaard, for example, says that it is possible that the knight of faith might have to 'transcend the ethical', and Nietzsche holds that authentic individuals will live 'beyond good and evil'. Thus, authenticity seems to have more to do with what is called the 'art of self-cultivation' than it does with ethics as traditionally understood.

7 Criticisms and prospects

Existentialism has been criticized from a number of different angles. One line of criticism holds that the emphasis on individual freedom and the rejection of absolutes in existentialism tends to undermine ethics; by suggesting that everyday life is 'absurd' and by denying the existence of fixed, binding principles for evaluating our actions, existentialists promote an 'anything-goes' view of freedom that exacerbates the nihilism already present in contemporary life. Camus' novel *The Stranger* (1942b), for example, has come under attack for glorifying immoral 'gratuitous acts' as a way of affirming one's own absolute freedom. In reply, supporters of existentialism have noted that the stance portrayed in the work is not at all typical of existentialist views, and that existentialism's ideal of freedom and its sense of the need for human solidarity after the 'death of God', far from undermining ethics, might provide a very good basis for a moral point of view in the modern world (see Existentialist ethics).

Other critics have tried to show that the basic picture of reality presupposed by existentialism necessarily leads to nihilism. Hans Jonas (1966) argues that existentialism, despite its avowed goal of overcoming Cartesianism, tends to introduce a new kind of dualism with its sharp distinction between humans (who are thought of as absolutely free centres of choice and action), and an inert, meaningless 'being' that is on hand for humans to interpret and

transform as they please. Not only does this extreme opposition exclude animals from the realm of beings with intrinsic worth, its view of humans as thrown into an indifferent universe seems to give us freedom only at the cost of making nothing really worthy of choice.

This line of criticism is closely connected to the claim, formulated by various postmodern theorists, that existentialism is still trapped within the assumptions of Humanism, a view now supposed to have been discredited. Humanism in this context means the view, central to modern philosophers from Descartes to Kant, that the human subject is immediately present to itself as a centre of thought and action, and that the rest of the universe should be thought of as a collection of things on hand to be represented and manipulated by the subject. Postmodern theorists claim that a number of intellectual developments in the last two centuries have made it impossible to accept this picture of the centrality of the subject. The semiotic theories of Saussure, for example, have shown how language tends to work behind our backs, controlling our capacities for thought and speech, and Freudian theory has shown how unconscious drives and desires lie behind many of our conscious thoughts and actions. Given these developments, it is claimed, we can no longer accept the idea that humans are capable of the sorts of self-transparency and self-determination that seem to be presupposed by existentialists like Sartre (see Postmodernism).

In reply to this objection, one might point out that most existentialists have been very critical of the Cartesian belief in the transparency of consciousness to itself. Such themes as being-in-a-situation, 'thrownness', embodiment and mystery show the extent to which many existentialists think of humans as embedded in a wider context they can never totally master or comprehend. Moreover, the existentialist description of humans as temporal beings whose 'present' is always mediated by what is projected into the future and retained from the past undermines any Cartesian conception of the immediate presence of self to self in self-awareness. Finally, as Sonia Kruks (1990) argues, postmodern theorists seem to have run up against a wall in their attempts to 'de-centre the subject'. Having identified the pervasive background structures that influence the thoughts and actions of subjects, these theorists now find it difficult to give an account of the kind of critical thinking they see as central to the postmodern stance. In Kruks' view, existentialists have much to offer postmodern theory in formulating the conception of a 'situated subjectivity' that will fill this gap.

It is not clear what the future holds in store for existentialism understood as a philosophical movement. Many of the ideas that sounded so exciting in Paris in the 1940s now seem terribly old-fashioned. Many of the more viable themes in existentialism have been absorbed into new philosophical movements, especially into hermeneutics with its emphasis on humans as self-interpreting beings (see Hermeneutics). While some existentialist writers have faded from the scene, others have become more and more influential (though not always *as* existentialists). There has been an explosion of interest in Heidegger and Nietzsche recently, and the works of Kierkegaard, Sartre and Beauvoir are widely discussed.

Whether or not existentialism as such will continue to thrive, it seems that there will always be a place for the style of critique of society and the concern with the concrete realities of life that are central to existentialist thought. As a reactive movement, existentialism challenged the uncritical assumptions of mainstream philosophy as well as the complacency of everyday social existence. In its more positive side, it attempted to counteract the tendency to self-loss in contemporary life by formulating a vision of the kind of coherent, focused way of living that would provide a basis for meaningful action. These certainly seem to be valuable aims, and it is likely that existentialist writers will always have important contributions to make toward realizing them.

Existentialist ethics

Central to existentialism is a radical doctrine of individual freedom and responsibility. On the basis of this, writers such as Sartre have offered an account of the nature of morality and also advanced proposals for moral conduct. Important in that account are the claims that (a) moral values are 'created' rather than 'discovered', (b) moral responsibility is more extensive than usually assumed, and (c) moral life should not be a matter of following rules. Existentialist proposals for conduct derive from the notion of authenticity*, understood as 'facing up' to one's responsibility and not 'fleeing' it in 'bad faith'. Authenticity, many argue, entails treating other people so as to encourage a sense of freedom on their part, although there is disagreement as to the primary forms such treatment should take. Some have argued that we promote a sense of freedom through commitment to certain causes; others that this is best achieved through personal relationships.*

1 Existential freedom

Existentialism has been described as a 'philosophy for living', an engagement with the realities of the human predicament. But some have argued that an existentialist ethics is impossible, on the grounds that the existentialist understanding of moral choice and value precludes advocating any particular choices and values. This charge is sometimes supported by citing (a) the variety of personal commitments - Christian, communist, even fascist - among writers in this tradition, and (b) the reluctance of some of these writers to express their commitments in moral terms (Kierkegaard sometimes seems to commend the person-of-faith's 'suspension of the ethical', and Nietzsche the 'higher' person's going 'beyond good and evil'). To assess these competing views, we need to understand (a) the existentialist emphasis on freedom and responsibility, (b) the resulting account of moral choice, values and rules, and (c) the ideal of authenticity.

Existentialism is not a sharply defined tradition. Here, we are concerned primarily with the views of Jean-Paul Sartre, but also with those of predecessors and contemporaries - including Kierkegaard, Heidegger and Gabriel Marcel - to the extent that these have affinities with Sartre's position. Central to the tradition is the idea of radical individual freedom and responsibility to which, as human beings, we are 'condemned'. This is not freedom in the sense of absence of constraints, for this varies from society to society. Nor is it simply the freedom to will which actions to perform. Rather, it is a person's freedom to 'make himself… since nothing foreign has decided what we are' (Sartre 1943: 554). We are responsible, therefore, for our characters and emotional make-up, and even for the situations in which we 'find ourselves', since circumstances only constitute a *situation* when interpreted by us in a certain way. Someone who interprets the mountain as a challenge is in a different situation from one who sees it merely as an obstacle. Such interpretations of the world are embedded in purposes for which we are responsible. Neither human beings nor the world, therefore, have a given nature or 'essence': it is through purposive activities that they become what they are.

Sartre spoke of our 'choosing' to be what we are, but others identify existential freedom with a capacity to stand back from our lives and change them. I may not have chosen my social situation, but I could reflect upon it, 'refuse' it and 'begin something else' (Merleau-Ponty 1945: 452). Although 'thrown' into an already interpreted world, we can, with 'resoluteness', become 'released' from the prevailing interpretations (Heidegger 1927: 163).

2 Values, responsibility and rules

From such accounts of freedom, existentialists have drawn conclusions concerning moral values, responsibility, and the place of rules in moral life.

(a) Values are, in a sense, 'subjective' functions of our interpretative activity rather than features of an independent reality. They are not, wrote Sartre, 'strewn in our path', but 'created' or 'invented'. This does not mean, however, that existentialists insist on a 'gap' between facts and values. Nietzsche (1886) denied that there are moral facts, arguing there are no facts at all, independent of human 'perspectives'. Values are *no more* 'subjective' than other features of the world, for even 'factual' descriptions are inseparable from evaluation. Values, as Heidegger stressed (1927), are not 'stuck on' to a world first articulated in a value-free manner, since all articulation reflects human 'projects' which are shaped by what matters to us, what we find worth pursuing.

It follows from this that the existentialist view of values is 'anti-foundationalist' (though see §4). There can be no

final justification for a particular value, since all justification presupposes an interpretative stance which is itself imbued with values. Some writers dramatize this 'predicament' by referring to the 'absurdity' which thereby infects our lives. It is not moral values themselves which are absurd, but the discrepancy between the serious commitment they require and the recognition that they lack any final foundation. (This 'absurd' discrepancy is distinct from the one, discussed by Albert Camus (1943), between our aspirations to knowledge and the world's 'refusal' to supply it - see Camus, A.).

(b) The existentialist view of moral responsibility is predictably demanding. First, for some writers, notably Kierkegaard, adoption of the moral point of view is itself an individual decision that cannot be dictated by reasons, since any such reasons would presuppose a commitment to that point of view. Even after it has been adopted, there remains a choice as to the *kind* of morality to follow. Sartre's wartime student, who must decide between joining the Free French and looking after his mother, is in effect having to choose between the 'collective' good and a 'morality of… personal devotion' (1946: 36).

Second, our responsibility allows for much less mitigation than is usually thought. We are, according to Sartre, 'without excuses' (1946: 34). The 'villains' in existentialist fiction often excuse their behaviour by citing their 'character' or the exigencies of their job, failing to admit that their 'character' and the demands incumbent on them are of their own making. Nor is my responsibility confined to what I *do*, for by *failing* to oppose a war, say, I have 'dirty hands' and share responsibility with those actually waging the war. Neither is it to the results of what *I* do that my responsibility is limited. By acting in a certain way, I give a green light to others to act in the same way, and hence bear responsibility for the results of their doing so.

It might be thought that for 'religious existentialists' our responsibility is reduced by the obligation to obey God's commands. But the tendency of these writers is to emphasize that faith itself is a free commitment and one, moreover, which reflects, rather than constrains, a person's moral values. My perception that it is God's command that I am obeying is therefore one for which I am accountable.

(c) Existentialists generally reject the familiar picture of morality as a system of rules or principles. This is not due to a predilection for motiveless *actes gratuits*, but for two other reasons. First, the familiar picture encourages people to go along with conventions and to respond to situations mechanically. One can 'do anything "on principle" and avoid all personal responsibility', Kierkegaard complained (1846: 85). Adherence to rules, moreover, detracts from the task of identifying what these situations really are, something that itself calls for moral deliberation since situations are functions of how circumstances are interpreted and evaluated (see §1). An obsession with following rules, then, implies abdication from responsible appraisal of our situations and deeds.

Second, the feasibility of basing decisions upon rules is much exaggerated. Moral rules are typically vague and, in many contexts, speak ambiguously. Sartre's student (see §2 (b)) can easily cite rules which, suitably construed, would endorse either of the courses of action contemplated. By their very nature, moreover, moral rules are tailored to recurrent, everyday situations, and are useless, therefore, in what Jaspers calls 'boundary situations'. How I should confront my death, for instance, is an issue so individual to me that the precedents set by other people can have no automatic bearing. Even much less dramatic circumstances can have a complexity and uniqueness which render the application of rules hazardous. As one of Simone de Beauvoir's characters puts it, 'I can't tell you [what to have done]… because I wasn't in your place' (1954: 646).

3 Authenticity

These claims about the nature of morality do not themselves provide practical guidance to the values and goals people should adopt. 'Anti-foundationalism' and hostility to rules may even seem to preclude this. If existentialism is to furnish a practical ethics, this will be on the basis of a notion, already visible in Kierkegaard's and Nietzsche's sketches of the 'subjective existing individual' and the 'overman' respectively, which later writers call 'authenticity'.

The authentic person is one who lives in clear, honest recognition of existential freedom. This is best understood in contrast with the various ways of being inauthentic that Sartre calls 'bad faith'. These are strategies for denying or disguising one's freedom and responsibility in order to minimize the 'anxiety' which full appreciation of these would induce. Inauthentic life, as Heidegger puts it, 'tranquillizes'. One such strategy is to regard oneself as being in the grip of unconscious drives; another is illustrated by the woman, in Sartre's example, who pretends that her

seduction by a man is something that is merely ‘happening’ to her (1943: 55-6).

The most common and insidious strategy, however, is that of identifying too closely with one’s ‘being-for-others’, with the images and expectations that other people have of one. Simone de Beauvoir (1949) complained of women’s tendency to match themselves with the image men have of them and then behave as women are ‘supposed’ to do (see Beauvoir, S. de). More generally, I surrender my ‘ownmost being’, as Heidegger calls it, when I do what ‘one does’, when I tailor my values and attitudes to those expected of me. I have surrendered to the anonymous ‘Them’, to Kierkegaard’s ‘Public’ or Nietzsche’s ‘Herd’. ‘Authentic’ is the translation of the German *eigentlich*, from a word meaning ‘own’. The authentic individual ‘owns’ and ‘owns to’ their life.

4 Reciprocal freedom

When Sartre says that an authentic decision cannot be ‘judged’, this seems to confirm the charge that authenticity is at best a recipe for how to ‘think and feel’, not for what ‘we ought to *do*’ (Warnock 1970: 125; original emphasis). But he also holds, qualifying his ‘anti-foundationalism’ apparently, that freedom is ‘the foundation of all values’ (1946: 51). This refers us to a theme stated succinctly by Jaspers, that ‘man becomes free only in so far as the other becomes free’ (1957: 85). This theme is inherited from German Idealists, like Johann Fichte, rather than from Kierkegaard and Nietzsche, whose heroes engage in solitary self-cultivation to the relative exclusion of concern for ‘the other’.

In contrast with his earlier view that people assert their own freedom at the expense of that of others, Sartre came to hold that ‘my freedom impl[ies] mutual recognition of others’ freedom’ (1983: 487). Although he writes that, in oppressing others, ‘the oppressor oppresses himself’, the point is not primarily a political one. The idea is that unless I recognize the freedom of others, I cannot properly appreciate my own and so live authentically. This is because my conception of myself is indelibly coloured by how I take other people to view me. Now I cannot suppose that they regard me as free unless I regard *them* as free. Hence my obligation to cultivate an authentic sense of myself as a free person commits me to cultivating in others a similar sense of their freedom. In Heidegger’s language, people exist authentically when each ‘frees the other in his freedom for himself’ (1927: 159).

But how is this cultivation of other people’s sense of their own freedom to proceed? For Sartre, it is primarily through commitment to large causes, such as resistance to fascism. But for others, it is in personal relationships of love and friendship that, in Marcel’s words, I ‘apprehend’ another person as free, ‘help him to be freed, [and] collaborate with his freedom’ (1935: 107).

The ideal of authenticity, it seems, does have broad implications for the treatment of other people, in which case the charge that existentialism cannot furnish a practical ethics is misplaced. That existentialists differ as to the precise implications of the ideal may reflect a human dilemma rather than confusion on their part. It is, in effect, the dilemma confronting Sartre’s student, for either of the actions he considers could be seen as honouring the freedom of others (in a way that his going off to peddle heroin to children could not). Existentialists, like the student himself, have no short answer to the question of which kind of concern - one for people at large, or one for those to whom one is intimately related - is the better expression of an authentic life. That is hardly cause for concluding that existentialism cannot make ‘any contribution to moral philosophy at all’ (Warnock 1970: 125).

Existentialist theology

Existentialist theology is a term used to describe the work of a number of theologians, chiefly from the twentieth century, whose writings were strongly influenced by the literary and philosophical movement known as existentialism. Because of the diversity of the movement, it is difficult to say much that is illuminating about existentialist theology as a whole. In general, however, these theologians attempt to understand God in relation to the situation of the concretely existing human individual. Their analysis of human existence is one that emphasizes the freedom of individuals to shape their own identities through choices, and the paradoxical, ambiguous or even absurd character of the reality that humans encounter. Religious faith is seen as closely related to feelings of alienation and despair; faith may grow out of such emotions or it may provide the key to overcoming them, or both these relations may be present at once.

Though the designation of any particular theologian as 'existentialist' is a controversial matter, Karl Barth, Rudolf Bultmann and Paul Tillich are among the more important thinkers whose work exhibits existentialist themes. The entire movement has been strongly influenced, directly or indirectly, by the nineteenth-century Danish philosopher-theologian Søren Kierkegaard, while the works of the Russian novelist Fëdor Dostoevskii and the German philosopher Friedrich Nietzsche, both from the late nineteenth century, have also been important.

1 Kierkegaard's critique of Enlightenment-inspired theologies

Though Kierkegaard lived from 1813 to 1855, his writings were not widely known outside Denmark until the end of the nineteenth century. As these works were translated, Kierkegaard became increasingly influential, both directly and indirectly through his impact on people such as Heidegger. Much of his influence stemmed from devastating criticisms of nineteenth-century liberal Protestant thought.

Kierkegaard was a Christian writer who saw himself as a kind of missionary, whose task was to 'reintroduce Christianity into Christendom' (1967, vol. 1: 160). He believed that the established churches of Europe had departed from genuine Christianity, which required a risky commitment to and willingness to suffer with the crucified Christ. These churches had instead developed a complacent religion that identified Christian faith with conventional ethical virtue. Kierkegaard felt that what was needed was the abolition of 'Christendom', the easy assumption that all born in Christian countries become Christians as a matter of course; Christianity requires a decisive commitment on the part of the individual. Kierkegaard believed that the rationalistic theologies that had come out of the Enlightenment provided a justification for 'Christendom' because of their underlying optimistic view of human nature. Such theologies assumed that humans had a natural capacity to gain religious truth on their own, and so the necessity of historical revelation as the foundation of faith was eliminated. They also de-emphasized human sinfulness by a tendency to reduce the religious life to a form of morality.

Kant (§11), for example, had attempted to develop a 'religion within the limits of reason alone', in which the essential tenets of Christian faith, a pure moral religion, could be derived from practical reason. Hegel (§8) had constructed a philosophical system in which the content of Christianity was supposedly justified by being philosophically developed and articulated. Schleiermacher (§7) had developed a theology in which the general religious experience of dependence became the foundation of faith. Though all of these thinkers attempted to find some continued role for historical revelation, the truth of any such revelation was for them something to be vindicated by showing that the revelation was in agreement with the conclusions of critical reflection. Revelation was thus subordinated to reason. In contrast, Kierkegaard attempted to make the categories of faith and revelation once again central for religious understanding.

2 Insights of Kierkegaard and other nineteenth-century thinkers

In *Fear and Trembling* (1843), Kierkegaard tries to show that the life of faith, exemplified for both Jews and Christians by Abraham, cannot be understood solely in ethical terms, since Abraham's faith was shown by an action that could not be ethically justified, namely his willingness to obey God by sacrificing his son Isaac. In *Philosophical Fragments* (1844), he goes on to argue that the 'Socratic' assumption that humans can achieve religious truth on their own is incompatible with the Christian view that humans are sinners who must be transformed and given the truth by God himself. This perspective is developed further in *Concluding Unscientific*

Postscript (1846), in which Kierkegaard describes Christian faith as involving a particular kind of inward passion, or 'subjectivity', that cannot be the result of philosophical reflection. The *Postscript* contains a thoroughgoing critique of the Hegelian claim to have achieved a systematic understanding of the whole of reality; it emphasizes the unfinished, historical character of human existence and the failure of thinking to reach objective certainty on existential concerns. The Hegelian system has difficulties both at the beginning and at the end: it cannot really begin, as it claims, with no presuppositions, because of the situated, interested character of human existence; and it cannot finally be completed, which means that it cannot be a system. A system requires a completeness and finality that human existence does not allow.

Kierkegaard does not deny objective truth; he affirms that reality is a system for God (that is, from God's point of view, reality is a system). When it comes to what he calls essential truth, however, he affirms that this truth can only be achieved by the existing thinker through passionate commitment. The person whose life is qualified by the right kind of 'subjectivity' may be said to be living truly even if that person believes things that are not objectively true. The truth of Christianity, which assumes that humans cannot achieve this kind of subjective truth on their own, is grasped in the passion of faith that is created by God within the person who encounters God in the historical figure of Jesus of Nazareth.

The centre of Christian faith for Kierkegaard is the incarnation. Far from wishing to prove historically that Jesus of Nazareth was God incarnate, Kierkegaard insists that faith does not require objective certainty; in fact, it thrives on the risk generated by objective uncertainty (see Faith §5). The idea of God becoming incarnate is, to us humans, the absolute paradox; as such it cannot be an object of proof. We come to believe in Christ only when we receive at first hand from him an awareness of our sinfulness and need of revelation. Since the object of faith is paradoxical, it necessarily appears 'absurd' and constitutes a 'possibility of offence' to the sinful self, which insists on holding on to its own autonomy. The believer, however, is not offended. To believers, Christ as the God-man is the truth, the truth that is at the same time 'the way and the life'. Thus, the true Christian does not seek speculatively to understand the incarnation, but to live as a follower of Jesus, who is for the believer both the redeemer and 'the pattern'. The believer must be willing to suffer with Christ and break with the established patterns of the world.

Though Kierkegaard provides the most important nineteenth-century background for existentialist theology, the figures of Dostoevskii and Nietzsche also deserve mention. Though independent of Kierkegaard, both emphasize the idea that human thinking is passionate and interested rather than completely objective and disinterested, and both emphasize the ways in which the universe does not appear to make sense to existing human beings. In *Notes from Underground* (1864), Dostoevskii highlights the way in which choice, even irrational choice, preserves our individuality and humanity, and in *The Brothers Karamazov* (1879-80), he powerfully presents the ways in which human suffering and evil seem to make no sense in a world God has created. Yet in such an ambiguous world our freedom is preserved, a freedom which God honours by approaching us in the humble figure of Christ.

Nietzsche not only emphasizes the interested character of human thought, but provides a challenge for theology by reinterpreting Christian morality as a morality of weakness, based on resentment and envy. He challenges the Christian to examine the unconscious motives that may lie beneath what is presented as Christian love, and poses the question as to whether God is a threat to human freedom and autonomy.

3 Twentieth-century existentialist theologians

Karl Barth (1886-1968) is both the earliest and the most influential of twentieth-century theologians indebted to existential thought. Barth's first major work, a commentary on Romans (1919), was forged in the disillusionment created by the First World War and clearly shows the influence of Kierkegaard and Dostoevskii. In this work, Barth challenged the optimism of liberal Protestant thought by attacking its assumptions that human beings could develop a natural knowledge of God and that Christianity could be vindicated as a higher evolutionary stage in the natural development of such knowledge.

Barth stressed instead the 'infinite qualitative difference' between a God who is 'wholly other' and human beings. The knowledge of God cannot be achieved through human religious experience, but is completely dependent on God's self-revelation. This revelation can be given no philosophical foundation, but is understood as true in the existential situation in which human beings encounter God. The Church must listen to the word of the living God,

before whom human religious systems and institutions are judged and found wanting.

Barth's emphasis on the transcendence of God won great respect because of his opposition to the Nazi attempt to give a theological justification of their racist and nationalist policies. Barth clearly saw the idolatrous character of National Socialism and became a leading figure in the protest of the Confessing Church. He largely authored the 'Barmen Declaration' (1934), which argued strongly that the lordship of Christ over the state must be acknowledged and that Nazi ideology must be judged in the light of God's transcendent revelation.

In his later writings, notably the massive *Church Dogmatics* (1939-67), which occupied most of the rest of Barth's life, there is a movement away from any overt reliance on Kierkegaard or other existentialist thinkers. In his later work, Barth emphasizes not only the 'no' that God pronounces against autonomous human religious and political striving, but the 'yes' that God graciously grants in Christ. All of the classic Christian doctrines are reinterpreted in a Christocentric manner, since the eternal Word of God has become incarnate in Jesus of Nazareth. That Word is still seen as a call to decision and commitment.

Rudolf Bultmann (1884-1976) was linked to Barth early on, but the two quickly distanced themselves from each other. Bultmann is equally renowned as a theologian and New Testament scholar, and his theological work reflects his insights as an inventor of form criticism, a discipline that studies the New Testament in the light of the situation of the early Church. Bultmann agreed with Barth that the 'quest for the historical Jesus' carried on by liberal Protestantism had failed to provide a foundation for faith, and that it was imperative to hear again the message of God as proclaimed by the Church. Unlike Barth, however, he saw the need for a radical translation of the message of the New Testament if it was to be heard by twentieth-century people.

As Bultmann saw it, the New Testament message is presented in mythical language that reflects the prescientific cosmology of the day. That message must be demythologized if it is to be meaningful to contemporary persons, and the key to this reinterpretation is provided by the analysis of human existence found in the early writings of Martin Heidegger. When the New Testament is read in this way, the offer of salvation is understood as an offer of a new form of authentic existence. Human persons must face the limits of human existence, especially their own death, without fleeing to some form of inauthenticity in which their being is identified with some objective entity in the world. Instead, humans must recognize that their authentic being lies in possibility, in their potentiality-to-be. In a way that is not completely clear, even to many of Bultmann's followers, this form of authentic existence is offered to humans in the historical figure of Jesus of Nazareth. History must here be understood as meaningful narrative (*Geschichte*), rather than as 'what actually happened', the object of scholarly investigation (*Historie*). What is important about Jesus is the 'historic' significance of the narrative, its meaning for the individual facing a decision, not the 'historical' (factual) accuracy of the narrative, regarding whichBultmann takes a critical, sceptical view.

Paul Tillich (1886-1965) differs from both Barth and Bultmann in being less tied to biblical exegesis and more overtly engaged in philosophical reflection. Tillich practised what he termed a 'method of correlation', in which the questions posed by human existence philosophically interpreted and the answers provided by religious revelation (also philosophically interpreted) were to be understood as mutually illuminating. In his analysis, God is understood as 'being-itself' or 'the ground of being' rather than as a supernatural being. The modern religious task in the West is to discover the power of being-itself, to find the 'God above the God of theism'. It is the 'God above the God of theism' who appears when the traditional God, understood as a distinct personal being, has died.

Tillich reflects the concerns of Nietzsche, Sartre and other existentialists that the traditional God of theism would limit human freedom and autonomy. The human task is therefore to confront a world of meaninglessness and discover 'the courage to be', the power that allows us to accept ourselves even when there is no personal God who accepts us.

For Tillich, the power of being-itself is mediated through 'symbols' that are said to participate in the power of being. For Christians, the story of Jesus can be such a symbol, but Tillich does not claim that the Christian symbols are unique or universal, and their truth does not lie in depicting the way things are objectively. The power of a symbol depends partly on the ability of a community for which that symbol functions to perceive that power.

4 Critical problems and lasting contributions

The diversity of views found in existentialist theology demonstrates that it cannot be defined in terms of particular conclusions. In relation to Christianity, it is useful to distinguish between thinkers such as Kierkegaard and Barth, who reformulated Christian themes to show their relevance to the human predicament, from those such as Bultmann and Tillich, who use Christian language to present 'existentialist' views radically different from traditional religious faith. Kierkegaard and Barth use new thought-forms creatively to express and make sense of classical religious convictions, while Bultmann and Tillich use traditional language to express very nontraditional views.

While some would argue that such theologies simply reflect the cultural and political situation of twentieth-century Europe, the attempt to relate religious concerns to the human existential predicament cannot be dismissed so easily. Existentialist theology reflects the perennial encounter between philosophical reflection and religious commitment and illustrates the power of each to shape the other. The existentialist theologian challenges the philosopher by highlighting the 'interested' character of human thinking, while the philosopher challenges the theologian to make sense of religious commitments in the light of all that humans know and experience.

Existentialist thought in Latin America

In Latin America the thought and teaching of José Ortega y Gasset have been very influential. Their influence leaves an important mark on the substance of existentialism. The most effective aspect of Ortega y Gasset's philosophical conception was his thesis that humans do not have a nature, only a history. It is this concept that encouraged Latin American thinkers to create their own original thought as a product of their concrete historical circumstances. This entry will deal with Latin American existence, unique in its historical concreteness, and from this general view will attempt to construct a metaphysical theory of Latin America's historical endeavour.

Given that all historicist conception involves values that are objective in nature, it is not surprising that Latin American existentialism was profoundly influenced by Max Scheler and Nicolai Hartmann, together with the existential analysis of Martin Heidegger. Consequently, in opposition to the phenomenologists with a Husserlian orientation, implicit in Latin American existentialism, there is a phenomenological methodology in the interpretation of history as culture in accordance with the analysis of the dialectics of the structure of history. This opposes all possible perceptions of pure essences which might precede existence. The essence of existence is seen as progressive, constructing itself as it is bypassed by historical events.

Both in terms of the search for an original philosophy, which could be reduced to a philosophy of history (for example in the Orteguian philosophy of life) and in terms of a Heideggerian approach, Latin American philosophy applies a phenomenological method in its analysis. This would explain the fusion of phenomenology and existentialism in the works of Latin American philosophers. All Latin American phenomenological-existentialist philosophical effort is a struggle between the analysis and interpretation of the European currents and their search for the historical realization of the autonomous Latin American being.

1 Existentialism and literature

Existentialist thought centres its philosophical speculation around concrete human existence, focusing on lived experiences, or *Erlebnisse*, and emphasizing the freedom of choice and the subsequent responsibility of the human being as self, or *être-en-soi*. The statement given by Jean-Paul Sartre that man is condemned to be free implies the necessity of 'engagement' with one's own life project. Because of these principles, many existentialist thinkers chose literature as a vehicle through which they could better express the search for the authentic self. This choice often caused some confusion between philosophy and literature, for example in the work of Sartre and Miguel de Unamuno, the latter undoubtedly the precursor of the trend of thought that can be identified as strictly existentialist. In fact, novelist and thinker, de Unamuno, coined the definition 'El hombre de carne y hueso' (the man of flesh and bone).

In Latin America, the existentialist search for authenticity was similar to the quest for an authentic national identity. Specific examples can be found in Puerto Rico, with its special political situation and the continuous intellectual struggle to defend Puerto Rican and Latin American culture in its development as Hispanic culture, set against North American culture, which is held to be alien and imposed on Puerto Rico by colonial imperialism. Hence, the existentialist vision of both humanity and life has been influential for writers, such as Edelmira González Maldonado (1923-) and Emilio Díaz Valcárcel (1929-).

González Maldonado is a well-known and well-respected short story writer, although her literary work is not very extensive. Her most important short story collections include, *Crisis* (1973), *Soledumbre (Solitude)* (1976) and *Alucinaciones (Hallucinations)* (1981). Her literary work has focused on the themes of humankind's loneliness and the limitations and ambiguities of language and the problem of interpretation between speaker and listener.

Crisis (1973) was the first attempt to express the concept and feeling of existentialist anguish. Argentine thinker Angel Casares who wrote the prologue for the book states: 'This book is, then, a piece of life, a life'. The title of *Soledumbre* is the deliberate use of an ancient word meaning both solitude and remoteness. *Soledumbre* is clearly an existentialist writing as it focuses on the concrete *hic et nunc*, the space and time of the literary work of art. Vital space and time are set against radical loneliness representing the horizon of the self. One of González Maldonado's short stories (1976), whose title is a quote from Martin Heidegger's *Unterwegs zur Sprache (On the Way to Language)* (1959), *Die Sprache spracht* (language speaks), shows with its play on words, the impossibility

of communication between human beings and establishes the dark dimension of existentialism. This dimension is the alienation which occurs with the loss of self and identity and the way in which the quality of being unique and authentic is lost within humdrum existence. In *Alucinaciones (Hallucinations)* (1981) the writer searches for the solution to metaphysical anguish in the realm of dazzling fantasy.

Emilio Díaz Valcárcel felt a deep commitment to his country and its problematic future. Díaz Valcárcel believed that the solution must begin with the construction of the self as a Puerto Rican Latin American, although he considered that Puerto Rican writers such as himself are trapped in the gap between cultural and national identity and political identity. His most important novel with the striking title of *Figuraciones en el mes de marzo (Representations in the Month of March)* (1972), is considered to rank alongside the works of García Márquez, Fuentes and Vargas Llosa. In this novel the protagonist, a mask for the author himself, struggles with two of the most significant existentialist concepts: freedom and authenticity. He is incapable of accomplishing the task of the construction of the self and is dominated by feelings of solitude and impotence in the face of his existence. He escapes by entering a realm of strange and often frightening fantasy in which he is persecuted by something monstrous, bizarre and terrible. He tries to maintain the ties that bind him to his country and his family, but the conflict between dreams, patriotism, love and the necessity of writing drive him towards a fantasmagoric fantasy, the parody of literature, and worse, solipsism. At this point, his writing falls into the existentialist black abyss of nothingness.

2 Relevant thinkers: Argentina

Carlos Astrada (1894-1970) used the ontology of Heidegger as a starting point and addressed many Marxist issues. He centred his thought on the idea of the risk implied by all metaphysical speculation. The game unleashes its own process within an existential scope. Astrada (1942) concerned himself with certain structures which were not thoroughly developed in the work of Heidegger, such as, the concrete composition of the ‘Dasein’ (being-here) and the relation of the ‘Dasein’ to things, before moving towards the Marxist dialectic in the latter stages of writing (1970).

Jorge Casares was professor at the University of Buenos Aires from 1953 to 1964 and after moved to the University of Puerto Rico. Mostly concerned with Heidegger, he emphasized three fundamental points in Heideggerian metaphysics: the loss of being as domination of thought, being in its totality and the loss by and for humans of their essence. These three points, tied in with other existentialist themes, are thoroughly explored in his work *Sobre la esencia del hombre (On the Essence of Man)* (1979).

Vicente Fatone (1903-62) was professor of cosmology and metaphysics at the National University of Litoral and of the history of religion at the National University of La Plata. He mostly concerned himself with the mystical experience and philosophical thought in India. He focused on the theme of liberty, which he interpreted from different existentialist viewpoints (1952; 1972). Fatone maintained: ‘I am nothing but my freedom; but I am not my freedom because I am not: I have to be’ (1948: 25). For Fatone, humanity is not free, but creates its own freedom, because liberty is not a property of the human being. It is a condition by virtue of which man becomes man and woman becomes woman. Towards the end of his life, he took up the theme of mysticism again.

Eugenio Pucciarelli’s existentialist roots lay in his interest in ontological, historical and aesthetic topics. A student of Alejandro Korn and Francisco Romero he was preoccupied with the sciences of the spirit. He was more distinguished for his teaching than for his written work. He maintained that metaphysical testimony - perception of the a priori conditions that make experience and morality feasible - is perceived through experience and morality.

Ismael Quiles (1958) was professor of philosophy at the University of Buenos Aires. A Jesuit priest, he edited the journal *Ciencia y fe (Science and Faith)* (1944-64). His thought is known as the philosophy of insistence. He was not a strict existentialist, but took advantage of certain Heideggerian concepts featured in *Being and Time* (1927) in his metaphysics of interiority in which humans are fulfilled through the knowledge of the world (be-in), of others (be-with) and of God as the absolute transcendence of all finitude.

Anibal Sánchez Reulet (1910-) wrote extensively on Husserl and Nicolai Hartmann. He followed, in part, Romero’s direction and was influenced by Ortega y Gasset. He was interested in the aspiration to transcendence in human existence as an affirmation of freedom through objective value judgments. For Sánchez Reulet this transcendence, in the end, becomes a question of transcending the historical conditions which determine the

finitude of existence.

Miguel Angel Virasoro (1900-66) was professor at the University of Buenos Aires and at the Universities of Córdoba, Bahía Blanca and Mendoza. Virasoro (1942) was influenced by Hegel and later, Heidegger. His work was thus an existentialist synthesis of Hegelian dialectics (1957). His starting point was the intuition of the finitude in the concreteness of existence (see Argentina, philosophy in).

3 Relevant thinkers: Brazil

Gerd A. Bornheim is not very well known internationally. He distinguished himself among scholars of existentialism in Brazil with *Sartre: metafisica e existencialismo (Sartre: Metaphysics and Existentialism)* (1971). He dealt with problems of an ontological nature and, to a certain degree, reaffirmed Hegelian ontology. He showed deep insight in unravelling the metaphysical aspect of Sartre's thought as he tried to expose the metaphysical underpinnings of the phenomenon of being.

Euryalo Cannabrava (1908-91), like many other Latin American thinkers, was attracted by the phenomenological-existentialist movement. He drifted towards logical neopositivism as he was interested in the philosophy of language and in the attempt to reduce philosophy to a method. His most important existential writings were *Descartes e Bergson (Descartes and Bergson)* (1938) and *Seis temas de espírito moderno (Six Themes of Modern Spirit)* (1941). In *Descartes e Bergson*, he attempted to surpass rationalism and vitalism. In 1956 he published *Elementos de metodología filosófica (Elements of Philosophical Methodology)* in which he revealed his increasing distance from Heidegger.

Vicente Ferreira da Silva's philosophical endeavours raised consciousness about the need for philosophizing in Brazil. He was one of the most important and enthusiastic followers of the existentialist movement. He wrote *Ensaios filosóficos (Philosophical Essays)* (1964) (see Brazil, philosophy in).

4 Relevant thinkers: Mexico

Adolfo Menéndez y Samara (1908-54) was deeply influenced by Heidegger and his question of being and its constant emergence from nothingness. In his youth he wrote *Dos ensayos sobre Heidegger (Two Essays on Heidegger)* (1939), which reveals a preoccupation with ontology. His early death did not allow the metaphysical-existentialist aspect of his work to develop fully.

José Romano Muñoz (1953) was one of the first disseminators of Orteguian thought in Hispanic America. His principal preoccupation was with finding answers to the questions of those who are more interested in wisdom than in science, such as: Who are we? What role do we play in the world? What is our fate? These questions brought him to the field of ethics which became his major preoccupation under the influence of Max Scheler and Nicolai Hartmann. His book, *Hacia una filosofía existencial: al margen de la nada, de la muerte y de la náusea metafísica (Towards an Existential Philosophy: at the Edge of Nothingness, Death and Metaphysical Nausea)* (1953) had a strictly existentialist perspective.

José Sánchez Villaseñor (1950) was a Catholic thinker, who worked on the thought of Sartre from a critical perspective, particularly with respect to the assertion of the absurd nature of existence. He was also a critic of the thought of Ortega y Gasset (1949) (see Mexico, philosophy in).

5 Relevant thinkers: Peru

Luis Felipe Alarco was a student of Alejandro Deústua (1849-1945), professor of philosophy at the University of San Marcos, Lima. Deústua (1967) defended a philosophy of creative freedom in which liberty is the basis of all social and moral values. Alarco is considered to be the initiator and catalyst of the philosophical movement in Peru. He was principally interested in the thought of Nicolai Hartmann. His inclination towards the philosophy of Hartmann was owing to his interest in overcoming the propaedeutic character of Heideggerian phenomenological analysis. His three most representative writings are *Nicolai Hartmann y la idea de la metafísica (Nicolai Hartmann and the Idea of Metaphysics)* (1943), *Lecciones de metafísica (Lessons in Metaphysics)* (1947) and *Ensayos de filosofía prima (Essays on Prime Philosophy)* (1951).

Alberto Wagner de Reyna (1939) studied in Berlin with Nicolai Hartmann and in Freiburg with Heidegger. His

first work focused on the thought of Heidegger. Later, in an approximation to Gabriel Marcel (1889-1973), he became interested in several existentialist themes, including the priority of existence over essence and commitment and engagement in one's own historical reality, that were useful to Catholic thought. He was one of the first to propagate the thought of Heidegger in Hispanic America. He focused his attention on themes that are typically Heideggerian such as death and care. He attempted to demonstrate that existential analysis meant to clarify beings as such and that temporality is the ontological condition of human existence.

6 Relevant thinkers: Venezuela

Ernesto Mayz Vallenilla (1925-) is a phenomenologist who deals with existentialist thought (1966), influenced by Dilthey and Heidegger. One of the themes that has interested him most is technology as a means of overcoming the finitude imposed by nothingness from a temporal perspective. For Mayz Vallenilla, technology has an ontological foundation in its utility, one of the ingredients of existence according to Heidegger, but also in the will to dominate.

Experiment

Experiment, as a specific category of scientific activity, did not emerge until the Scientific Revolution of the seventeenth century. Seen primarily as an arbiter in theory choice, there was little, if any, analysis of experimental techniques or, the ways in which data become transformed into established facts. Philosophical analysis of experiment was typically simplistic, focusing on the role of observation alone as the foundation for experimental facts. This was challenged by Thomas Kuhn who stressed the importance of background theory and beliefs in all perception, including (its role in) scientific experiment. This interconnection between theory and experiment severely undermined the idea that experiment could stand as an independent and objective criterion for judging the merits of one theory over another.

In the 1980s new philosophical analyses of experiment began to emerge, emphasizing the ways in which experiment could be seen to have a life of its own embodying activities that could supposedly be understood without recourse to theory. Factors important in the evaluation of experimental results as well as the ways in which laboratory science differs from its theoretical counterpart became the focus for a new history and philosophy of experiment. Consequently, further debates arose regarding the relationship of experiment to theory, and whether it is possible to provide a methodological framework within which experimental practice can be evaluated.

1 Historical overview

Although the use of trial and error methods to establish scientific results can be traced back to the Greeks, experiment as a specific category of scientific activity did not emerge until the Scientific Revolution of the seventeenth century. This occurred partly in response to the development of precision instruments like the telescope, microscope and pendulum clock, but also as a result of the growth of scientific academies that provided laboratory environments. Galileo's work on hydrostatics was perhaps the first instance of what we now think of as the experimental method. He showed how experiments on bodies floating in water could be used to confirm Archimedes' principles and refute those of Aristotle. Francis Bacon was the first to provide a classification for various kinds of experiment including the concept of a crucial experiment, which came to be thought of as a decisive test of one theory over its rival (see Crucial experiments).

Even though experimental demonstration was an important component of the Scientific Revolution its primary function was thought to be that of an arbiter in theory choice. There was little, if any, analysis of experimental techniques. Issues about the epistemic status of experiment were typically assimilated to debates about the nature of experience in general. Emphasis on experiment was associated with empiricism; consequently, not everyone saw experiment as the foundation for scientific knowledge. Descartes, for example, relied heavily on experiment in his scientific work; yet in his philosophical writings deduction from first principles or innate ideas took precedence over empirical inquiry as the ultimate ground for knowledge.

2 Experiment as distinct but subordinate

Although experiment occupied a role distinct from theory, at least in historical and philosophical writing on science, theory continued to hold the dominant position. Even the most respected physicists, such as James Clerk Maxwell and Albert Einstein, devoted little if any attention to experiment in their writings about science (even though Maxwell was a gifted experimenter and Einstein emphasized the role of thought experiments in the development of relativity theory (see Thought experiments). Philosophical and historical accounts focused either on crucial experiments, such as Fresnel's diffraction experiments which decided in favour of the wave over the corpuscular theory of light (see Optics §1), or experiments that were associated with important discoveries, for instance those that led Roentgen to the discovery of X-rays, or Millikan's measurements of the charge on the electron.

Although these kinds of experiment were discussed in articles and textbooks, much of the intricate detail that represents such an important part of experimental work, detail that is extracted from notebooks and investigations of laboratory practices, was excluded. As a result, the experiments were characterized in a highly idealized way, embodying none of the difficulties often encountered by working scientists in establishing specific results.

Philosophical analysis of experiment also presented a simplistic view of its function and its relationship to theory. Twentieth-century positivism (or logical empiricism) emphasized the importance of observation as the secure foundation for science, but provided no analysis of experiment itself. Nor did it question the authority of observational reports. For the positivists, the meaning of a particular term was its method of verification, and many considered simple observation reports entered in a log book or protocol to be the ultimate basis of science (see Meaning and verification; Theories, scientific §§1-2; Logical positivism §4). Because all of science had to be understood in terms of empirical concepts, experimental procedures were sometimes appealed to as providing meanings for theoretical terms. One way of doing this was to identify terms like ‘electric force’, which is not empirically observable, specifically the operations necessary to measure the force, with the instrument or pointer readings that indicated its presence. This particular method of assigning meanings or values to scientific concepts was known as operationalism (see Operationalism). Despite the importance of testability and observation reports for establishing meaning there was no analysis of how experimental results and procedures became stabilized and validated.

The emphasis on definitive observational reports was challenged most influentially by Thomas Kuhn in *The Structure of Scientific Revolutions* (1962) (see also Hanson, N.R.; Popper, K.R.). He argued that not only scientific experiments but also the interpretation of all experience was heavily dependent on background theoretical knowledge (see Observation §§3-4). Kuhn’s thesis, known as the theory-ladenness of observation, entails that two individuals, such as Kepler and Tycho Brahe, who hold different theories about the sun literally see different things when they observe it. One of them sees a stationary body around which the earth moves while the other sees a moving body rotating around the earth. As a result neither simple experience nor experiments (including crucial experiments) can provide a neutral ground for theory choice. The analysis of experiment that Kuhn provides is really an account of how psychological factors influence perception. Consequently, theory becomes the focal point from which the interpretation and relevance of all experimental data is assessed.

In response to theory-ladeness, sociologists of science denied that appeals to nature in the form of experiment were ever decisive in deciding between competing theories. Such decisions, and even the interpretation of data, were made simply on the basis of social and political factors that often stood outside the laboratory domain. Philosophers responded by accepting that observation was theory-laden while maintaining that those theories nevertheless corresponded to a determinate world, which, if characterized correctly, would reveal its true nature.

3 The rise of experimentalism

The emphasis on experiment as a distinct field of philosophical inquiry began with the work of Ian Hacking (1983). He urged philosophers to focus on activities like the building and operation of instruments, calculation and measurement, the creation of phenomena and manipulation of entities in the laboratory, all of which are part of an experimental culture that is distinct from the theoretician’s world and from questions that have traditionally dominated philosophy. As a result, a new set of philosophical issues arose: for example, how should we characterize the relationship of experiment to theory in light of Hacking’s claim that ‘ experiment has a life of its own’; is there a methodology of experiment that can furnish validating procedures and constraints for evaluating results; and how do the credibility of particular instruments and the theories implicit in their operation bear on the integrity of laboratory events?

Hacking stressed the independence from theory of various aspects of experimental practice, such as viewing and manipulating microscopic images and specimens, the manipulation of entities such as electrons using electron guns, and the creation of particles in accelerators. He claimed that most of these images and entities are robust and survive even radical theory change. Knowledge of them derives from their low-level causal properties (for example, mass, charge, and so on) that are involved in the design and operation of devices used to measure, observe and create them. However, it is not simply the fact that these entities can be experimented on that attests to their reality; they must be capable of being manipulated and used as tools in the investigation of other aspects of nature, not simply observed or detected in the laboratory. Hence, the goal is not just understanding the nature of these entities, but using them to transform nature. As Hacking (1983) remarked about electrons - ‘If you can spray them then they are real’.

Despite the importance of isolating experimental practice in this way, questions have arisen concerning the interplay of experiment and theory and whether Hacking’s reliance on manipulation can underwrite the realistic

status of experimental entities. A much greater theory than that of low-level causal generalization is needed to differentiate, for example, between specific kinds of particle interactions that take place, even in a straightforward case like the identification of a particle in a cloud chamber. In this context one must appeal to a scaffolding of theoretical knowledge that comes from electrodynamics, mechanics and so on, in order to distinguish an electron from a negatively charged pion. Similarly, when a beam is produced using a simple ruby laser, the apparatus utilizes causal properties such as the mass and charge of the electron, but in order to understand simulated emission, the very basis of laser action, we need the quantum theory of the electron. A great deal of theory, over and above the theory about how the apparatus produces the beam, is required before one can meaningfully say that one is producing laser light by the manipulation of electrons.

In addition to simply describing the activity of manipulating particles, interpretive controversies often arise in cases where different groups evaluate experimental results and practices in different ways. Experiments done in the late 1970s to investigate the existence of charmed quarks involved photon, neutrino and hadron beams. One group of physicists thought that quarks were the constituents of hadrons, and that, in that sense, quarks were being manipulated in order to investigate charm. Another group, who thought quarks were merely fictional entities that provided a mathematical description of hadron collisions, saw the manipulation of the beams as having nothing to do with quarks; still another group with a different account of quarks also had a different interpretation of the practice of manipulating hadron beams.

What the examples show, and indeed what an emphasis on experiment has clarified, is the degree of complexity involved in the relationships among experiments, phenomena, instruments and theories. The idea that an experiment can serve as an independent judge in a theoretical dispute is not necessarily vindicated by showing how experiment has a life distinct from theory. Very often an analysis of experimental work exposes subtle theoretical influences not obviously present in textbook histories. When Heinrich Hertz successfully produced electromagnetic waves in his laboratory in 1888, it was against the backdrop of competing views about electromagnetism from Maxwell and Helmholtz. The experiment acquired a different meaning and had different implications for British scientists (who saw it as definitive confirmation of Maxwell's electrodynamics) than it did for Hertz. There was no ambiguity that what were produced were electromagnetic waves, but the velocities of the waves contradicted a fundamental component of Maxwell's theory, a result ignored by the British, but which caused Hertz great concern. It was not as though the British could explain away the experimental anomaly, or that Hertz had reasons unknown to the British causing him to distrust his results. Hertz saw the experiments as proving that electrical action is propagated in space rather than at a distance, but did not sanction any particular account of how that process took place. Although Hertz's anomalous results were never explained, similar experiments done by others established the velocities predicted by Maxwell's theory, to Hertz's satisfaction. As we can see, the transition from laboratory event to experimental fact is one that involves more than 'reading the book of nature'.

Establishing an experimental fact also involves evaluating the interpretation of an experiment; this involves determining the legitimacy of a particular result, together with assessing the validity of background assumptions that are brought to bear in understanding the meaning and significance of experimental outcomes. There are competing philosophical views about the justification of an experimental result and the role it plays in the broader theoretical context. The evidence model emphasizes the connection between a particular result as the manifestation of a determinate world and a theory that attempts to describe that world. Thus Allan Franklin (1986) suggests that there is a set of strategies explicated in terms of Bayesian confirmation theory that determines the validity of an experimental outcome and the role it plays in deciding between competing theories (see Confirmation theory; Inductive inference §3). On this view, it is simply a fact whether or not a particular outcome occurs and whether it is relevant in a theoretical context. In contrast, the social model advocated by Andrew Pickering (1984) and others proposes that the way a piece of evidence is interpreted and judged relevant depends on sociological and political factors including the interests of specific groups of scientists who wish to promote particular theoretical views, rather than on its reflecting a determinate way the world is. Consequently there is no unique characterization of experimental evidence. Others like Peter Galison (1987) recognize a role for both natural and social constraints. By showing how experiment involves not just the work of a single scientist or group, but a complex community of subgroups, each with its own goals and standards, Galison shows the diversity that constitutes experimental work and the various levels at which the interplay between natural and social concerns emerges.

The philosophy of experiment recognizes that experimental practice is an autonomous part of a broader scientific

culture with distinct problems and issues. The literature has focused primarily on two kinds of concern: first, the 'how to' of experiment, which emphasizes laboratory practices and techniques that differentiate it from theoretical work; and, second, the epistemological debate about the proper characterization of experiment and its implications for scientific realism and theory confirmation. The latter presents two options. One involves attempts to provide a framework within which to understand and codify that practice - a 'theory' of experiment. The other focuses on the local nature of experimental practice by presenting it in a way that defies a unitary view or method describing how specific results are reached and legitimated. Emphasis on experiment has thus produced a new theoretical debate about what a proper philosophy of experiment and science ought to be.

Data, with their experimental dimension, play the role of observation but only in witness for claims about phenomena.)

Experiments in social science

Within social science the experiment has an ambiguous place. With the possible exception of social psychology, there are few examples of strictly experimental studies. The classic study still often cited is the Hawthorne experiments, which began in 1927, and is used mainly to illustrate what became known as the 'Hawthorne Effect', that is, the unintended influence of the research itself on the results of the study. Yet, experimental design is often taken within social research as the embodiment of the scientific method which, if the social sciences are to reach the maturity of the natural sciences, social research should seek to emulate. Meeting this challenge meant trying to devise ways of applying the logic of the experiment to 'non-experimental' situations where it was not possible directly to manipulate the experimental conditions. Criticisms have come from two main sources: first, from researchers who claim that the techniques used to control factors within non-experimental situations are unrealizable with current statistical methods and, second, those who reject the very idea of hypothesis-testing as an ambition for social research.

1 The logic of the experiment

The intention of the experiment is to organize inquiry so that it bears decisively on hypotheses and the theories from which they are deduced. The classic means of achieving this is to set up a controlled comparison between two groups which are as alike as possible at the outset of the experiment. Only one of the groups is subjected to the experimental treatment. Thus, if there is a difference in the experimental outcome, then this can only be due to the experimental treatment. Control is typically achieved by matching subjects and randomizing their allocation to the experimental or to the control group so that possible confounding factors are excluded as possible explanations of the outcome.

John Stuart Mill's formalization of the general logic of the experiment (Mill (1843) was used as a framework for Durkheim's efforts to formulate sociology as a discipline with a properly scientific method. In his *The Rules of Sociological Method* (Durkheim 1895), he proposed the 'method of concomitant variation' as the means by which the causes of 'social facts' can be identified (see Mill, J.S. §2). In his later study, *Suicide* (Durkheim 1897), applying this logic to relevant official statistics, he identified variations in the suicide rate among various subgroups and, by eliminating alternative explanations, arrived at what he regarded as the social causes of different types of suicide.

Distinctive about Durkheim's work was his attempt to exploit the logic of the experiment in non-experimental situations; that is, situations in which it is impossible directly to manipulate causal and possible confounding factors. His own procedure, using official statistics, was to identify variations in the suicide rate among ever finer delineated subgroups, and a precursor of what became known as 'variable analysis' which is now one of the standard social research methods (see Durkheim, É.).

2 Variable analysis

However, the refinement of what became known as variable analysis owes more to the work of Lazarsfeld and his colleagues than directly to Durkheim (Lazarsfeld and Rosenberg 1955; Campbell and Stanley 1963; Stouffer 1950). Immediately after the Second World War, mainly in the USA, considerable effort was devoted to developing research methods which, though used in non-experimental situations, would provide a means of approximating to experimental designs and so make empirical research more decisive for social theory. This period led to the refinement of social survey and questionnaire design, measurement techniques and statistical multivariate methods for the analysis of social survey data.

Unike the classic experimental design which directly allocates subjects to control and experimental groups, in variable analysis, typically using survey data, the grouping of respondents takes place after the data have been collected. In place of matching and randomization, relationships of interest to the researcher are examined by holding constant other factors which may influence such relationships. For example, suppose a researcher is interested in the effects of ethnicity on voting choice, then the task is to isolate the effects of ethnicity given that other factors, such as occupation, gender, age, income, level of education, and more, may also have an effect on voting. Grouping the respondents into such other categories, and then determining the strength of the association

between ethnicity and voting within each of them, is seen as holding constant any effects on voting choice which may arise from factors other than ethnicity. However, there is a limit to the number of factors which can be handled in this way before the statistical measures used to determine the relationship become unstable and, of course, only those factors on which data have been collected can enter into the analysis.

3 Problems with the experimental model

More seriously, the procedures of variable analysis depend heavily upon the random selection of respondents in order to neutralize the effects of possible confounding factors, whereas in the classic experimental design control is done through matching and the random allocation to control and experimental groups. In non-experimental research, the random selection of cases is an approximation to experimental randomization if it can be assumed that the population from which the sample is drawn is homogeneous; a reasonable assumption when dealing with a population of seeds, plants or germs, but less secure when dealing with populations of human beings. Indeed, one of the founding presuppositions of social science is that individuals are not isolated but related in a myriad of ways. It becomes harder to make the assumption that samples of individuals - which is the typical method employed in survey research - selected for their distinctiveness on one variable will vary randomly on others. Indeed, Lieberson makes the point that although most data in social research are non-experimental in origin, they are ‘treated as if they were truly experimental data…sliced, chopped, beaten, molded, baked, and finally artificially coloured until the researcher is able to serve us proudly with a plateful of mock experiment’ (Lieberson 1985: 4). The burden of this critique of the use of the experimental model in social research, is that controlling fails to deal adequately with selectivity in the control variables. That is, social research deals with situations in which people, apart from their birth, have not been randomly assigned to their respective social worlds. Social processes of selectivity operate throughout life among subgroups, with varying effects and with different magnitudes, with the result that controlling in social research is not a ‘benign procedure’ since it takes little account of these selectivity processes.

Lieberson’s arguments direct attention to what it is matching and randomization are intended to provide, namely, a basis for sustaining the *ceteris paribus* conditions which govern any theoretical hypothesis. Selectivity processes, under current practices of social research, cannot be controlled which means that such *ceteris paribus* assumptions cannot be sustained. Similar considerations, though from a very different perspective, emerge in consideration of even laboratory experiments using human subjects. It was noted earlier that one of the claims to fame of the Hawthorne experiments was the discovery of ‘reactive effects’, that is, effects of the experiment itself on its results. Although this was not a standard laboratory experiment, none the less, it did provoke serious considerations of the ways in which the very organization of experimental situations could itself violate *ceteris paribus* assumptions by introducing uncontrolled ‘reactive effects’ (Rosenthal and Rosnow 1969, especially the paper by Boring who suggests that such ‘reactive effects’ were originally the rationale underlying the idea of the control group). Among such ‘reactive effects’ are the meanings and understandings that subjects themselves bring to the experimental situation. As Cicourel 1964) points out, experimenters have to make assumptions about basic social processes in order to select subjects, organize their experimental activities, give them directions, and so on, but which are not explicated, let alone controlled. Rarely is the question of what is commonly perceived by subjects and experimenter as invariant about the social scene of the experimental situation addressed. As Milgram’s (1974) experiments on obedience show, subjects themselves give meanings to experimental situations, for example, as normal, as involving legitimate activities and trusting in the experimenters that they will come to no harm, and so on. So much so that they are ‘willing’ to engage in actions, such as supposedly inflicting intense pain on others, out of obedience to what is perceived as the normative structure of the experimental situation.

A broader issue of debate relevant to the experiment in social science is the nature of the social sciences themselves; a debate which, of course, enters into epistemology. The experimental model is very much a hypothesis-testing procedure and, in this respect, intended as a means of building general theories. However, as discussed earlier, in social science research the direct manipulation of the factors and the experimental conditions is not possible. There are approaches which question whether this model is appropriate given that the experiment presumes that a great deal is known about the phenomena in question in order that the method may be brought to bear decisively on hypotheses. Approaches which draw their inspiration from less positivistic theories of knowledge, such as symbolic interactionism and ethnomethodology, emphasize the importance of studying the social world as a naturally occurring world without the intervention of experimental or quasi-experimental

methods (Hughes 1990).

Explanation

Philosophical reflections about explanation are common in the history of philosophy, and important proposals were made by Aristotle, Hume, Kant and Mill. But the subject came of age in the twentieth century with the provision of detailed models of scientific explanation, prominently the covering-law *model, which takes explanations to be arguments in which a law of nature plays an essential role among the premises. In the heyday of logical empiricism, philosophers achieved a consensus on the covering law model, but, during the 1960s and 1970s, that consensus was challenged through the recognition of four major kinds of difficulty: first, a problem about the relation between idealized arguments and the actual practice of explaining; second, the difficulty of characterizing the underlying notion of a law of nature; third, troubles in accounting for the asymmetries of explanation; and, four, recalcitrant problems in treating statistical explanations.*

Appreciation of these difficulties has led to the widespread abandonment of the covering-law model, and currently there is no consensus on how to understand explanation. The main contemporary view seeks to characterize explanation in terms of causation, that is, explanations are accounts that trace the causes of the events (states, conditions) explained. Other philosophers believe that there is no general account of explanation, and offer pragmatic theories. A third option sees explanation as consisting in the unification of the phenomena. All of these approaches have associated successes, and face particular anomalies.

Although the general character of explanation is now a subject for philosophical debate, some particular kinds of explanation seem to be relatively well understood. In particular, functional explanations in biology, which logical empiricists found puzzling, now appear to be treated quite naturally by supposing them to make tacit reference to natural selection.

1 Early history

Thinking about explanation goes back at least to Aristotle, whose discussion of four kinds of causation in the *Posterior Analytics* can properly be viewed as distinguishing modes of scientific explanation (see Aristotle §9). In the modern period, the writings of Hume, Kant and Mill offer many insights on causation, laws and regularities in nature that, sometimes explicitly, sometimes implicitly, propose doctrines about the character of scientific explanation (see Hume, D. §2; Kant, I. §§4-7; Mill, J.S. §5). However questions about scientific explanation became sharply focused in the mid-twentieth century, with the emergence of an orthodoxy about scientific explanation, which, despite its later demise, stands as one of the most significant achievements of the movement known as ‘logical empiricism’ (see Logical positivism §4). The writings of Karl Popper (1959), R.B. Braithwaite (1953), Ernest Nagel (1961) and especially, C.G. Hempel (1965), articulate an influential conception. Namely, scientific explanations are viewed as arguments in which a statement describing the fact (or regularity) to be explained is derived from premises, at least one of which is a law of nature (see Hempel, C.G. §3). The underlying idea is that scientific explanations provide understanding by showing that the phenomena to be explained should be expected as a consequence of the general laws of nature.

2 The covering-law model

One important and much-discussed species of scientific explanation according with this general conception is *deductive-nomological* explanation (D-N explanation). In cases of this type, the argument is deductive, so that the statement describing the phenomenon to be explained (the *explanandum*) is a deductive consequence of the premises advanced in giving the explanation (the *explanans*). D-N explanations may be provided for explananda that describe particular facts or for explananda that announce general regularities. In the former case, there is a simple schema which exhibits the form of the explanation

$$\frac{\begin{array}{c} C_1, C_2, \ldots, C_n \\ L_1, L_2, \ldots, L_m \end{array}}{E}$$

where the statement *E* is the explanandum, describing the fact to be explained, the statements $L_1, L_2, \ldots, L_m$ are laws of nature, and the statements $C_1, C_2, \ldots, C_n$ describe particular facts (such as initial conditions). It is not hard to construct arguments that accord with this schema and which seem to explain their conclusions: derivations

in classical Newtonian dynamics that deduce the trajectories of bodies from force laws and initial conditions supply many examples.

Not all explanatory arguments are deductive. The logical empiricist orthodoxy admitted *inductive-statistical* explanations (I-S explanations) as well as D-N explanations. In an I-S explanation, the explanandum is inferred inductively from premises at least one of which is a probabilistic law, for example a statement that assigns a value to the probability with which a particular trait is found among members of a specific class. Thus, to cite a famous example of Hempel's, we may explain why a child, Henrietta, contracted measles, by noting that she has been in contact with another child, Henry, who has measles, and that a large percentage of children who come into contact with measles' patients (say 99 per cent) subsequently come down with measles. Imitating the schema for D-N explanation, we can present this modest derivation as follows:

Henrietta has been in contact with Henry, and Henry has measles.
The frequency with which children in contact with measles' patients subsequently acquire measles is 99 per cent.

$$\frac{\qquad\qquad (0.99) \qquad\qquad}{\text{Henrietta has measles}}$$

Here, the rule indicates that the inference from premises to conclusion is inductively strong, rather than deductively valid; the figure in brackets (0.99) reveals the strength of the inference. I-S explanations have to meet several requirements. First, the numerical strength of the inductive inference must be high (close to 1). Second, the explanans must meet a requirement of maximal specificity: there must not be known further premises which, if added to the explanans, would change the strength of the inference - as, for example, the inductive reasoning would be modified if we knew that Henrietta had received a measles' shot, and that children given such shots have a very low probability of acquiring measles.

Plainly, the explanations that scientists and others actually put forward do not look much like these stripped-down arguments. The logical empiricists claimed only that the everyday provision of explanations could be reconstructed by identifying arguments of D-N or I-S form, and that these reconstructions brought into the open what it was about the explanations that enabled them to fulfil their function. In the 1940s and 1950s, many scholars were happy to concede that the covering-law model of explanation, which assimilated explanations to arguments with laws among their premises, worked well as a reconstruction of explanations in the natural sciences - especially in physics and chemistry - but there were important debates about the application of the model to the social sciences and to explanation in everyday life. Controversy focused in particular on the activity of historical explanation. Historians construct detailed narratives that appear to explain particular events - the outbreak of the American Civil War or Henry VIII's dissolution of the monasteries. If the covering-law model is correct, then a proper reconstruction of these accounts must expose general laws. Are there indeed general laws in history? Or are the general laws that underlie historical explanation simply psychological laws that connect the motivations of historical actors with their actions (see Explanation in history and social science)?

3 Four kinds of difficulty

Troubles with history aside, the covering-law model appeared remarkably successful, a rare example of a convincing solution to a philosophical problem. Yet, in the 1960s, it came under sustained attack, and, by the end of the decade, it had been almost entirely abandoned. Four separate kinds of consideration contributed to this swift reversal of fortune.

First was a complaint, articulated by Michael Scriven (1962), that perfectly satisfactory explanations can be given, and understood, by people who are quite ignorant of the covering-laws that are essential to the supposed reconstruction. It is easy to explain to a friend why there is a mess on the floor by pointing out that your arm knocked the open ink bottle off the desk at which you were writing. Perhaps it would be possible for a knowing philosopher of science to cite the general laws that govern the behaviour of the bottle and the spilled ink, but this knowledge seems entirely irrelevant to the episode in which the chagrined mess-maker explains what has occurred. At the heart of Scriven's complaint lay the recognition that the covering-law model had failed to show how the idealized derivations that supposedly highlight how the explanatory work is done are adapted, in specific local situations, to transmit understanding from one person to another. Without a *pragmatics* of explanation, an account of how the ideal arguments that fit particular logical forms relate to what people actually do in giving explanations, it was possible to challenge the claim that the structures exposed by the logical empiricists reveal the crucial

features that make the explanation successful.

A second difficulty resulted from continued inability to provide a satisfactory account of natural laws. From the earliest formulations of the covering-law model, its champions had insisted that not every generalization counts as a law. So-called *accidental* generalizations cannot discharge any explanatory function: it may be a timeless truth about the universe that all ball games played by a red-haired left-hander who forgoes lunch are won by the opposite team, but that accidental generalization sheds no light on the outcome of any particular game (see Laws, natural §2). Prior to Nelson Goodman's formulation of a cluster of difficulties surrounding counterfactuals, induction and laws (1956), the problem of distinguishing laws from accidental generalizations appeared an interesting challenge to the logical empiricist project (see Goodman, N. §3). Once the depth of Goodman's 'new riddle of induction' had become apparent, it seemed impossible to find a solution within the constraints that empiricists allowed themselves (see Induction, epistemic issues in).

A third trouble emerged from the recognition that, even if the distinction between laws and accidental generalizations could be drawn, the covering-law model would still be too liberal. Introducing an example that was to become famous, Sylvain Bromberger (1966) pointed out that the model is blind to certain asymmetries in explanation. We can explain the length of the shadow cast by a flagpole by deriving a statement ascribing the pertinent numerical value from premises identifying the height of the pole and the angle of elevation of the sun, together with the law of the rectilinear propagation of light. This derivation fits the D-N schema beautifully. The trouble, however, is that we can produce a modified argument, according equally well with the D-N schema, by interchanging the premise that identifies the height of the pole with the conclusion: the height of the flagpole is deducible from the length of the shadow, the elevation of the sun and the law of rectilinear propagation of light. This new derivation does not seem explanatory, for it appears wrong to explain the heights of poles (or, more generally, the sizes of physical objects) in terms of the measurements of the shadows they cast. Scrupulous about appealing to causation, logical empiricism had tried to construct an account of explanation without invoking causal notions that would offend Humean sensibilities (hence, in part, the difficulty of characterizing natural laws). Bromberger's critique suggests that the omission of causal concepts assimilates cases that are importantly different: after all, it is tempting to characterize the difference between the two derivations by pointing out that the height of the flagpole *causes* the shadow to have the length it does, but that the length of the shadow does not cause the flagpole to have the height it does.

Perhaps the most influential difficulty, was the fourth, which focused on the failure of the account of statistical explanation. Alberto Coffa (1974) probed the conditions required of I-S explanation, revealing that they involved an essential reference to the state of knowledge, which made it impossible to develop a concept of a true inductive explanation. Coffa's critique complemented the work of Richard Jeffrey (1969), who had earlier argued that it is possible to explain individual events that do not have high probability in the light of background conditions, and thus that the high probability requirement was also defective. At the same time, Wesley Salmon (1970) worked out, in considerable detail, an account of statistical explanation that, like Jeffrey's, rejected the thesis that explanations are arguments. Central to Salmon's account was the idea that we explain by citing probabilistically relevant information. In the early versions of his model of statistical explanation, Salmon proposed that probabilistic explanations gain their force from the recognition that the probability that an individual has a property has been raised. Schematically, the information that a is F helps explain why a is G when the probability of something's being G is increased if that thing is F (more exactly: $\mathrm{P}(G/F) > \mathrm{P}(G)$). In this way, Salmon was able to respond to a difficulty noted earlier by Scriven - we may explain the fact that the mayor has paresis by noting that he previously had untreated syphilis, even though the frequency with which untreated syphilitics contract paresis is small (around 15 per cent). On Salmon's account, noting that the mayor had untreated syphilis gives an enormous boost to the probability of his having paresis, raising it from the baseline figure of close to 0 to about 15 per cent.

4 Picking up the pieces

Salmon's account of explanation was deliberately motivated by the felt need to allow for explanations in the indeterministic contexts of contemporary physics. His approach dovetailed neatly with attempts, like those of Patrick Suppes (1970), to fashion a conception of causality that would no longer be restricted to deterministic situations (see Causation §4; Determinism and indeterminism). From 1970 to the present, one important strand in

contemporary theories of explanation has taken explanation to consist in delineating the causes of events, and has tried to honour Humean concerns about the invocation of causality by providing a theory of causation that will define causal relations in statistical terms. The simplest account of probabilistic causality would propose that *A* is causally relevant to *B* just in case $\mathrm{P}(B/A) \neq \mathrm{P}(B)$. Unfortunately, this account is too simple. As Hans Reichenbach pointed out in the 1950s the inequality will obtain when *A* and *B* are both effects of a common cause (Reichenbach 1956). Thus further conditions must be imposed to identify the statistical relations constitutive of probabilistic causation.

Since the 1970s a number of different proposals have competed to inherit the position of orthodoxy once occupied by the covering-law model. Most popular have been causal approaches to explanation, and, initially, proposals to ground explanation in a detailed conception of probabilistic causality promised to answer (or sidestep) the four principal difficulties outlined above. However, it has proved remarkably difficult to work out a satisfactory account of explanation along these lines, and a number of critiques, most notably that by Nancy Cartwright (1983), have cast doubt on the viability of the enterprise. Faced with powerful objections, champions of causal approaches to explanation have pursued one of two options. One is to continue to honour Humean concerns about the causal relation, and to seek an analysis of causation that will not make use of metaphysical notions that empiricists consider dubious. The most thorough attempt to carry out this programme has been undertaken by Wesley Salmon (1984), who has attempted to develop Reichenbach’s account of causation in terms of the fundamental notion of mark transmission. The alternative approach is to declare victory by taking some causal notion as an unanalysed primitive, resisting Humean scruples about how we might know how to apply this notion as misguided (perhaps the proposals of Humphreys (1992) and Cartwright (1989) should be viewed as embodying this approach).

One evident attraction of the causal programme is that it provides an immediate response to the problem posed by the asymmetries of explanation. However, not all current theories view explanation as a matter of tracing causes. In recent years, Bas van Fraassen (1980), Peter Achinstein (1983) and Peter Railton (1981) have all made important contributions to the pragmatics of explanation, and the first two authors have defended the view that the enterprise of seeking substantive necessary conditions that apply across all contexts in which people seek and give explanations is misguided. The danger is that such pragmatic theories of explanation reduce the enterprise to triviality. For any explanation-seeking question and any proposition we choose, it seems that we can construct a context in which that proposition is licensed as an adequate (or even a perfect) explanatory answer to that question (see Kitcher and Salmon 1987, and, for a response, Lloyd and Anderson 1994).

A third cluster of positions stays close to the covering-law model’s conception of explanations as arguments, proposing that explanatory arguments are not distinguished singly but emerge from the best way of systematizing our body of knowledge. Michael Friedman (1974) and Philip Kitcher (1981) have developed (different) accounts of explanation that take arguments to be explanatory if they belong to a system of arguments that best unifies our beliefs. One virtue of this approach is its ready provision of an analysis of theoretical explanation; its principal difficulties lie in formulating appropriate criteria for unification and for addressing the asymmetries of explanation.

The present debate echoes themes from earlier chapters in the history of philosophy. Hume’s scruples about causation loom behind some efforts to articulate causal theories of explanation, those who oppose Hume on causation (like Cartwright) sometimes seem to harken back to Aristotle, and the unification approach has made an explicit connection with Kant. Perhaps these affinities suggest that contemporary debates about scientific explanation turn on larger metaphysical questions that need to be confronted directly (see Unity of science).

5 Functional explanation: a recent success story

Ironically, after the fragmentation of the consensus on the covering-law model of explanation, considerable progress has been made on studying a species of explanation that, despite careful studies by Hempel and Nagel, was always somewhat difficult for logical empiricist orthodoxy. Biologists often appear to explain the presence of a trait or structure by identifying its function, and it is not clear how such explanations should be assimilated to a D-N (or an I-S) schema. Thanks to pioneering work by Larry Wright (1976), contemporary philosophers of biology are largely agreed on a central idea: functional explanations are abridged versions of explanations in terms of natural selection. The identification of the function is thus seen as picking out the kind of selection pressure that causes the trait (or structure) to become originally established (or, maybe, to be maintained). The details of this idea are worked out in different ways by different authors, but the selectionist (or etiological) account of functional

explanation appears to provide a philosophically satisfactory reconstruction of parts of biological practice (see Evolution, theory of; Functional explanation).

A possible moral of the comparative success in studying functional explanation is that philosophers may be too ambitious in seeking general theories of explanation. Pragmatists, like van Fraassen, sometimes suggest that there are many different kinds of successful explanation, and that there may be no interesting general conditions that all must meet. Perhaps the most fundamental issue confronting the theory of explanation today is whether it is reasonable to seek a theory of explanation across all contexts and all epochs or whether the study of scientific explanation should be more local, concentrating on specific types of explanation.

Explanation in history and social science

Historians and social scientists explain at least two sorts of things: (a) those individual human actions that have historical or social significance, such as Stalin's decision to hold the show trials, Diocletian's division of the Roman Empire, and the Lord Chief Justice's attempt to reform the English judicial system; (b) historical and social events and structures ('large-scale' social phenomena), such as wars, economic depressions, social customs, the class system, the family, the state, and the crime rate. Philosophical questions arise about explanations of both kinds (a) and (b).

Concerning (b), perhaps the most pressing question is whether explanations of this sort can, ultimately, be understood as merely explanations of a large number of individual human actions, that is, as a complex set of explanations of the first kind, (a).

A causal explanation is an explanation of something in terms of its event-cause(s). Some explanations under (b) appear not to be causal explanations in this sense. There are two ways in which this appears to happen. First, we sometimes seem to explain a social structure or event by giving its function or purpose. This seems to be an explanation in terms of its effects rather than by its causes. For example, it might be claimed that the explanation for a certain social custom in a tribal society is the way in which it contributes to social stability or group solidarity. An explanation of a thing in terms of its effects cannot be a causal explanation of that thing. Second, we sometimes seem to cite social structure as the explanation of something. Whatever a social structure is, it is not itself an event, and since only (it is often said) events can be causes, such a 'structural' explanation does not seem to be a causal explanation.

A second question, then, about explanations of kind (b) is whether some of them, at any rate, are genuinely non-causal explanations, or whether functional and/or structural explanations of this sort can be seen as special sorts of causal explanation.

Explanations of kind (a) are a proper subset of explanations of human actions generally. Although some of the discussion of these issues began life as a distinct literature within the philosophy of history, it has now been absorbed into philosophical action theory more generally. Even so, a question that remains is just which proper subset of human actions are the ones of interest to the historical and social sciences: how can we discriminate within the class of human actions between those in which historians or social scientists have a legitimate interest and those outside their purview?

1 Holistic explanation

Many explanations in history and social science are explanations of large-scale events or structures such as wars, invasions, economic depressions, social customs, the class system, the family, the state, and the crime rate. A plausible thought is that these large-scale phenomena are merely patterns, or complexes, of individual actions, that the former are, in principle, ontologically reducible to the latter. This idea is sometimes captured by using the terminology of wholes and parts (see Mereology). Large-scale social events or structures are wholes, whose parts are the individual actions which constitute them. If this is so, then explanations of such large-scale social and historical phenomena are nothing more than complexes of explanations of those constituent actions of individuals which are the former's parts.

The term 'methodological individualism' is ambiguous (see Ruben 1985). Sometimes it is said to be the view that social wholes are nothing more than the sums of their parts. In this sense, it is not a thesis about language, that is, about the translatability without remainder of the language of social science into the language of individual psychology, although some writers have expressed it in this form. Nor is it a thesis about the methodology of social scientific practice, as its name might misleadingly suggest. It is a metaphysical thesis about what social phenomena really are, namely that they are just, or are wholly constituted by, individual persons with beliefs, desires, and other mental states, who stand in various relations with one another. This states the metaphysical thesis both in terms of identity and constitution. It is controversial whether the numerical identity and constitution relations are the same relation, and no statement of methodological individualism carefully delineates these two alternatives.

At other times, methodological individualism is described as a view about explanation: that the explanation of social facts is ultimately in terms of individual psychological facts (perhaps with purely physical facts added to the psychological ones). Stated in this way, one needs an account of social fact, in order to clarify the scope of the claim. What makes a fact a *social* fact? Presumably, social facts are not only facts about large-scale social phenomena: the fact that LaGuardia was a mayor is a social fact, because a social property, being a mayor, was true of that person. LaGuardia was himself not a large-scale social event or structure, and being a mayor is a property, neither an event nor a structure, large-scale or otherwise. Presumably, the fact that he was a mayor is a social fact, because being a mayor is a social property. So, in the end, methodological individualism as a view about explanation will need a perspicuous account of social property.

The important point, though, is that the metaphysical doctrine of methodological individualism does not, by itself, warrant any conclusion about the explanation of social facts. No such inference, from a metaphysical premise to an epistemological conclusion, could be valid without the addition of further premises. The methodological individualist thesis about the explanation of social facts in terms of facts about individuals would require some additional argument independent of the metaphysical thesis, in order to claim credibility.

So even if it were true that social wholes were nothing more than the ‘sums’ of individual actions, nothing immediately follows about the explanation of the former in terms of the latter. This point is further strengthened by the reminder that, whereas full constitution (and identity, if this is a distinct relation) is an extensional relation, explanation is non-extensional. That is, if {a and b} fully constitute w, and if a = d, b = e, and w = x, then {d and e} fully constitute x. How we describe constituents and what they constitute is not relevant to the truth of constitution (or identity) claims.

But this is not the case for explanation. With explanation, description matters: something can be explanatory or get explained when described in one way but not in another (see Explanation). Even though red is the colour of ripe strawberries, one might be able to explain why bulls charge at certain flags waved in front of them by the fact that the flags are red, but not by the fact that the flags are the colour of ripe strawberries. So it may well be that even if a social whole, say a war or an economic slump or the state, is nothing more than, is wholly constituted by, the actions of individuals, no explanation of the war or the slump or the state, could be adequate, even in principle, if expressed in the language of individual action. The relationship between the metaphysical truth of methodological individualism (if it were one) and the parallel methodological individualist thesis about ultimate explanation in the social sciences seems far more complicated than writers on these issues have typically assumed (see Methodological individualism §2, 3).

2 Functional and structural explanation

There is a ‘strong’ view that all explanations of large-scale social phenomena are functional explanations. Even if this view is false, it seems undeniable that there are at least some functional explanations in history and the social sciences (see Functionalism in social science §1). Certain customs, practices or institutions in a society might be explained by the role they play: religion; etiquette; bureaucracy; education or the state might be explained by their function for a society or for a specific group within the society in question. There seem to be functional explanations in biology as well, but the parallel between biology and social science on this issue is controversial, and it is better, therefore, to consider functional explanation in social science and history on its own, without considering the issue in biology and attempting to establish a general account of functional explanation, equally applicable to both fields.

Functional explanation in social science should be sharply distinguished from purposive (or intentional) explanation of individual human action. In the latter case, explanation is by way of the beliefs and desires or intentions of the agent. It has sometimes been alleged that functional explanation in social science also requires reference to mental states such as belief and desire, but mental states attributable to a group as a whole rather than to individual persons. Such an implausible view, with its notorious idea of a group mind, seems unnecessary, if we refuse to assimilate functional and purposive explanation. The former does not require reference to any mental states whatever, whether of an individual or of a group.

Are functional explanations a type of causal explanation? It might seem not, since such explanations seem to be in terms of the beneficial effects of a thing rather than in terms of its cause(s). But one plausible suggestion is that,

for an adequate functional explanation, there must be some causal 'feedback' loop: if education is to be explained by the way in which it helps a certain group retain power, then it is insufficient that education merely leads to the group's retaining power. If that were all there were to it, we would have an ordinary causal explanation of the group's power retention by the existence of the system of education.

On the contrary, what we had hoped for was the explanation of the education system in terms of the group's retaining power. On one view of the matter, to have the latter explanation, the group retaining its power must itself lead, by a causal loop, to further expansion or entrenchment of education. As such, we can see how the fact that education has the result of a group's power-retention is explanatory of the education itself, since education having this effect is itself a cause of more such education. Perhaps the stronger the group gets, the more it reinforces and develops the educational system. Education's effect further strengthens the system of education itself. We can also see, on this account of functional explanation, that functional explanation is merely a more complicated kind of causal explanation, involving a feedback loop in the causal chain (Elster 1983).

What about explanations in which social structure of some sort is cited as what does the explaining? How could these be causal explanations? For example, the kinship structure in a specific society might be said to explain why certain persons do and do not marry other persons to whom they are related in certain ways. One way in which to understand these cases might be to distinguish more carefully just what it is that one is explaining. Does the social structure explain some token event, like Tom marrying Rita, or does it explain some more general structural fact, like the fact that men must marry their dead brother's male-childless wife? If the former, then presumably the kinship system by itself cannot explain the specific marriage of Tom to Rita: the beliefs and wants of Tom and Rita, at the very least, will have to be included. Social structure cannot have an effect on the agents' behaviour directly; its effect must be mediated through, or combined with, the psychology of the agents. These mental states must figure in the explanation, and they will ensure that the explanation of the specific marriage is an ordinary causal explanation (see Structuralism in social science §1).

On the other hand, if what we are explaining is the structural fact about levirate marriage, then that feature of the kinship structure might follow from certain other features of the kinship structure, in the sense that the fact can be derived, or follows, from them. Writers in this tradition of explanation, basing themselves on themes and modes of explanation in the philosophies of Hegel and Marx, often speak of the underlying 'logic' of the social structure working itself out, thereby signifying that such explanations are akin to logical deductions (Zeleny 1980). In something like this sense, we could 'explain' some theorem of Euclidean geometry by deriving it from axioms and definitions. In the case of structural explanations in the social sciences, social structures are sometimes said to have their own dynamic, based on what they essentially are, and to develop according to their own inner laws or tendencies. If the concept of explanation were to be extended in this way, then there may well be structural explanations in social science which are not causal explanations. Even so, the thought that all explanations of events are causal explanations remains undisturbed; whatever such structural explanations are explanations of, they do not seem to be events in any sense.

3 Individual action explanation

Even if history and social science sometimes explain structures or events which are irreducible to individual actions and events, it is undeniable that they sometimes at least do engage in explanation of the actions of specific individual persons. What kind of explanations are these action explanations?

There are two 'grand' traditions in the philosophy of history and social science that supply an answer to this question, one represented (*inter alia*) by John Stuart Mill and Carl Hempel, the other by Wilhelm Dilthey, William Dray, and Peter Winch. The traditions' conventional names conjure up too many other views, which bear no logical connection to their views on action (see Action), so one can call the first tradition simply 'the causal tradition', and the second, 'the non-causal tradition'. By the former, the thesis intended is that every human action is to be explained by its causes, which are to be found, at least in part, in the mental states of the agents; by the latter, one understands any thesis which gives some other account of action explanation. This latter tradition is something of a catch-all. It is sometimes called 'hermeneutic', because many non-causal theorists liken explaining human action to interpreting a text. It is also sometimes called the 'interpretative' view, since it tends to stress the way in which action needs to be interpreted in order to be rendered intelligible. A specific version of this view is called 'contextualism', since it focuses on the societal norms or rules in the social setting in which the agent acts,

with which we can interpret what he is doing as an action of one kind or another. For example, it is only because there exist certain religious rules, or rules about banking, that we can say of someone that what they are doing is celebrating mass or cashing a cheque.

There are at least three distinctions required, in order to make any progress in deciding between these views. The first is between a mere bodily movement and an action. A person's hand may move, or their finger bend, without them moving their hand or bending their finger. The former may not be actions, things they do, and their explanation may not include any of their mental states at all. They might, for example, be merely reflex 'actions'. Even if mental states are included in their explanation, it may still not be actions which are being explained. Fear may cause my pupils to dilate; St Thomas' example is that of lust causing a man's erection. Neither the dilation nor the erection are the actions of a person. These latter explanations are not within the scope of social science at all, but rather of biology.

The second and third distinctions both have to do with what is sometimes called 'explaining under a description'. Explanation is, as claimed above, non-extensional; how something is described matters to whether it explains or is explained by something else.

The second distinction is between the intentional and non-intentional descriptions of action. On one plausible account of action individuation, what we explain are not just actions, but actions under some specific description or other. For example, every action will have an indefinitely large number of unintended effects, and the action can always be redescribed as the action having such-and-such an unintended effect. Theories of action explanation focus on explanation of actions under their intended descriptions. Once an explanation of action under its intended description is found, an explanation under its unintended description will be quickly forthcoming: it is just that the action as intended happened to have such a causal consequence.

The third distinction is between the action under its basic and its non-basic descriptions. (Non-basic descriptions can be either intentional or unintentional.) A man flexes his finger, pulls the trigger, shoots the gun, kills Smith, and executes a criminal. He executes the criminal by killing Smith; he kills Smith by shooting the gun; he shoots the gun by pulling the trigger; he pulls the trigger by flexing his finger. 'Flexing his finger' is the basic description of the action, if there is no other description of the action such that he flexes his finger by doing the action described under that other description.

The causal tradition, deriving from Hobbes and Hume, is the view that every action is to be explained, *inter alia*, by the mental states that cause it. The mental states may be only part of the full explanation of the action, but they are a necessary part. Metaphysically, this view about explanation is consistent with, but does not entail, physicalism: such rationalizing mental states may or may not be physical states (see Materialism §1).

On the causal view, the item that is explained is an action only if the mental causes not only cause the movement but also rationalize it, make it the rational thing to have done in the circumstances, relative to the agent's beliefs and desires. Rationalizing and causing are two distinct relations and provide two distinct requirements. On the causal view, the mental states that explain an action must both cause and rationalize it. On the traditional causal view, such a mental state must include a belief and a desire. This is the old Humean view of rationality as instrumental: an action is rationalized if it can be 'justified' in terms of what the agent believes they need to do in order to satisfy their desires (see Hume, D. §3). On other accounts, such a mental state may be an intention rather than a belief and desire pair. An agent's doing A can be explained by their intention to do so, if such an intention both causes their doing that action and makes it rational for them to do it (Ayer 1967; Gardiner 1978).

Since the non-causal tradition is, as has been described, something of a ragbag, let us select one strand from many possible ones. Often, non-causal theories focus on explanation of action occurring in an alien culture. How can we understand, or make sense of, what someone from such a society is doing, if it makes no obvious sense in our own terms? The answer surely is that we must know the rules and norms of that society, in order to interpret what they are doing, to endow their movements with sense and significance. We must, as it were, go native. If we are seeking to explain action under its intentional description, then we must know what the intentions of the agent are, and one can know the latter only by knowing the rules and norms of the society which give rise to, or at least make possible, the having of such intentions. Movements of one's body can only be given meaning in terms of such rules; one's hand movements can only constitute a writing of a cheque, in the light of regulations about banking.

And what is true of alien societies is true of our own; our own behaviour only acquires social meaning or significance, in the light of our own social rules and conventions (Dilthey 1976; Winch 1958).

The non-causal view seems plausible as a view about at least some non-basic action. So-called social actions are just actions under non-basic social descriptions. A person moves their hand (if they are acting, then it is not just that their hand moves). To understand their moving of their hand as their writing a cheque, one must cite, *inter alia*, the rules and regulations of banking. In order to do that, the explainer will need to cite, or suppose, the existence of a social institution, that is, banking. Social rules and institutions may only be relevant to action explanation at the level of non-basic descriptions of action. The non-causal view explains the possibility of giving social descriptions of action.

The causal theory, on the other hand, seems to be doing at least two different things. First, it accounts for the differences between mere bodily movement and intentional action. Second, given that the action performed was of a certain kind, it offers an explanation of why the agent acted in that way.

4 In virtue of what is an action of interest to the historian or social scientist?

Some actions will be of no possible interest to the social scientist. On 17 July 1995, I went into my garden and picked some sour cherries. Such an action certainly has an explanation: I desired some sour cherries and I believed that by picking some fruit from a specific tree in my garden, I could obtain some. Given the circumstances, it is hard to see how an explanation of that action could be of any interest to the social scientist. Other cherry pickings might be, in different circumstances. But that picking was not. Why should that be so?

It is important to see that this question is not the same as another question, with which it is sometimes conflated: which actions are social actions? Whether or not an action is a social action (as so described) can be determined a priori. Some action descriptions are social: writing a cheque, celebrating a marriage, witnessing a will. That is, it is logically or conceptually necessary for there to be a society, and certain rules or conventions, in order for persons to engage in actions of that description. Some philosophical disputes can be understood as disputes about whether certain action descriptions are social, for example, ‘speaking a language’.

We need here another distinction: between action types and singular action tokens. An action type is a universal, which has many possible instances. Stalin moving his left thumb is an action type, since there could have been many such movings by him. An action token is an individual instance; it is an unrepeatable, dated item. Stalin moving his left thumb at a specific time is an action token.

Do social scientists explain action types or action tokens? One might suppose that to explain why Hitler annexed Austria in 1938 is to explain an action token; to explain why investors withdrew their bank deposits in 1929 is to explain why some action type had many instances. However, another way to consider this might be to say that social scientists only ever explain types, but that sometimes they explain why an action type had at least one instance (why there was at least one annexing of Austria by Hitler in 1938), and at other times why an action type had many instances (why there were many withdrawals of bank deposits by investors in 1929).

Now, not all social action, whether type or token, is of any interest to the social scientist. Not only will they be uninterested in explaining why I picked those sour cherries, they might equally be uninterested in explaining the social action token, my writing a cheque at a particular time for sour cherries. Further, they may have no interest in explaining why the social action type, writing a cheque for sour cherries, has many instances. They might be interested in explaining the origins and development of the system of capitalist agriculture, but that is not the same as an explanation of any action, type or token, one or many, made possible by that institution (unless, perhaps, methodological individualism is true).

So only some social actions and only some non-social actions (whether types or tokens) are of interest to the social scientist. Which ones are they? Those, presumably, which are thought to have consequences of social significance. But what kinds of consequences are those? I do not think that one can ultimately make sense of the idea of ‘consequences of social significance’ except via an account of ‘consequences for the wellbeing or ill-being of a large number of individuals’. That latter concept has itself nothing irreducibly social about it. This is not to deny that the social scientist will also be interested in giving explanations of historical and social events and structures, nor is it to argue that such explanations must be in principle reducible to explanations of individual actions of

significance. It is merely to say that there is no way in which to circumscribe which sorts of actions the social scientist will want to explain other than by using an ultimately ethical notion of the wellbeing of individuals. It is, of course, consistent with this that the wellbeing of an individual will itself include the satisfaction of their need for relationships with other persons.

Fa

Fa *is a technical term in a variety of Chinese philosophical traditions. As a noun it means 'standard' or 'norm', and, by extension, 'law'. As a verb it means 'to be in accord with'. The disagreements among the various indigenous schools tended to focus on the origin and nature of* fa, *whether it is an order or pattern within things or an external pattern to which things conform. When Buddhism entered China, translators often used* fa *for rendering the Sanskrit term* dharma*. Depending on context, the Buddhist term could refer to true teachings, moral duty, phenomenal reality or rule.*

Like other philosophical terms, *fa* originally had an ordinary use in the Chinese language. As such, *fa* appears as a noun or a verb, suggesting either a standard to be met or the action of meeting that standard. Chinese philosophers differed over the external or internal nature of *fa*. Some maintained it is internal to things, part of their natural expression. Others held that *fa* is an external standard to which things normatively conform. Daoist philosophy tended to favour the internalist view; for example, Laozi used *fa* as a verb in maintaining that the *dao* itself 'accorded with' things as they naturally are (see Daodejing). Most other classical Chinese philosophers, however, used the term primarily as a noun to express a norm or standard.

Because the social, moral and political dimensions of human experience were central to Chinese systems of thought, philosophers often analysed norms relevant to the harmony of the state. Generally, the Chinese thinkers assumed the ruler to be responsible for setting and enforcing these standards. In such contexts, the term *fa* assumed a meaning close to that of the English term 'law' or, more specifically, 'penal law' (see Law, philosophy of; Law and ritual in Chinese philosophy). The Confucians and Legalists were especially inclined to view *fa* in such a manner.

For Confucius, social order arises from the practice of 'ritual' or 'propriety' (*li*) rather than law. Social harmony derives from each person's following the appropriate forms of basic human relations. If the conditions are right and the ruler is a person of sufficient charismatic virtue, Confucius maintained, then the society will organize itself harmoniously without legal sanctions. However, the Confucians also recognized that such ideal conditions do not necessarily prevail. When harmony breaks down, the ruler must enforce certain minimal standards of social behaviour through penal law (*fa*). In short, *fa* compensates for the inadequate practice of ritualized human interaction (see Confucian Philosophy, Chinese).

The Legalists, as represented by Han Feizi for example, characterized the role of *fa* differently. For them, *fa* is not a last resort, but instead the very foundation of the harmonious state. According to the Legalists, the state evolves out of the authority of the ruler and that ruler's capacity to establish a system of laws enforced by sanctions. For the Legalists, therefore, *fa* is neither part of the natural order (as the Daoists generally maintained) nor a back-up system for the virtuous charisma of the ruler (as the Confucians held).

The Legalist philosophy was perhaps the first systematic attempt in China to deal with the state independently of discourse about virtue or morality (see Legalist philosophy, Chinese). It stressed rule by law rather than rule by virtuous people. The Legalists argued for a universal legal system applying even to the ruler who originally established the laws. In a pragmatic vein, the Legalists maintained that government office should be assigned on the grounds of the candidates' practical talents and skills rather than education or virtue. This was, however, a strict totalitarian system of penal law in which offenders were not re-educated but were immediately (and by modern standards severely) punished. Although the strict Legalist philosophy was generally discounted as too harsh and inflexible, its ideal of *fa* endured as a central philosophical category within Chinese political theories and practices.

Buddhism brought a new layer of meanings to the term. When the Chinese began to translate Indian Buddhist texts two thousand years ago, they used the Chinese word *fa* to render the Sanskrit term *dharma*. The Buddhist term itself has several facets of meaning, including 'real (that is, non-delusory) phenomenon', 'true teachings', 'moral duty' and 'rule'. The match between the two terms was not perfect. At the time of its introduction, Buddhism was understood by the Chinese to be a philosophy akin to Daoism (see Buddhist philosophy, Chinese). It is helpful, therefore, to consider how the Daoist notion of *fa* relates to the Buddhist *dharma*.

Both Daoism and Buddhism aim to understand phenomena for what they are in themselves, without their being coloured by human or personal ideas of 'usefulness'. There are vast differences between Daoist and Buddhist practice, however. In Daoism, the focus is on observing the natural pattern or way (*dao*) of things, of seeing human beings as part of a larger natural process (see Dao; De). In Buddhism, on the other hand, the focus is on introspection and the eradication of the ego-centred projection of delusory contexts that lead one to interpret phenomena as 'mine', as 'permanent' and as 'desirable.' The Daoists and Buddhists share, however, the idea that if one sets right one's relation with the world, social morality will follow spontaneously. Specifically, for the Chinese Buddhists, if one eradicates the ego, one can experience the phenomena (*fa*) as they are in their own contexts without distortion. This experience will confirm the true teachings (*fa*) of Buddhism. Without ego, one will enact a spontaneous morality (*fa*). To achieve the proper attitude for the introspection leading to the eradication of ego, the monastic community sets social rules or laws (*fa*) that nurture detachment. When viewed in this light, we see how the different meanings of *dharma* in Buddhism are related and how the Buddhist term *dharma* could be construed as being consistent with aspects of the term fa, especially in its Daoist sense.

Fackenheim, Emil Ludwig (1916-)

Fackenheim is best known for his account of authentic philosophical and Jewish responses to the Nazi Holocaust. Fackenheim's thought, indebted to German philosophy, always had a practical, existential purpose. He aimed, consistently, to show how philosophical and theological thought could pay attention to lived experience in order to gain the understanding it sought. In this way, he exposed the varied ways in which thought and life, ideas and history, are interdependent. Philosophical and religious thought are grounded in historical experience and give direction to that experience; life is the ground of reflection and derives its meaning from it.

Fackenheim was born in Halle, Germany. Although aware of the dangers of Nazi persecution, he left Halle for Berlin, where in 1935 he began rabbinic studies at the Hochschule für die Wissenschaft des Judentums. After *Kristalnacht*, Fackenheim fled to Scotland and finally to Toronto, where he completed his doctorate with a dissertation on the doctrine of substance in the thought of the medieval Islamic authors known as the Sincere Brethren of Basra (see Ikhwan Al-Safa'). Four years later, having served as a congregational rabbi in Hamilton, Ontario, he began to teach philosophy at Toronto. He spent the post-war years studying German Idealism. This period culminated with the publication of a book on Hegel's treatment of religion. In this early period he defended faith and revelation. Understanding revelation and the faith it engendered as a divine-human encounter, Fackenheim took that encounter to be the ground of genuine religious life. After 1966-7, Fackenheim turned his attention to the memory of the Nazi death camps. He came to see the radical evil that erupted there as a threat both to reason and to faith. His defence of reason and faith became increasingly historical as he interpreted the continuity of religious faith as part of an authentic philosophical and religious response to the Nazi atrocities. Fackenheim remained in Toronto until his retirement and subsequent emigration to Israel in 1982.

Fackenheim's work and thought are united by several interrelated themes. The first of these is the existential relevance of philosophical and theological thought. This was a central attraction of existential philosophy: thinking is not detached from life; it arises in a concrete situation and is a committed response to that situation. Fackenheim shunned antiquarianism as he immersed himself in the great philosophers of the past, from Plato and Aristotle and Plotinus to Kant, Fichte, Schelling, Hegel and Heidegger. His aim was to grasp and grapple with the central issues of the present.

One of those issues is the conflict between reason and revelation. Stimulated by the thinking of Soren Kierkegaard, Martin Buber, and later Franz Rosenzweig, Fackenheim struggled with the challenges made by modernity and modern philosophy to the very possibility of faith and revelation. First, there is modern secular philosophy and thought, the challenge of figures like Feuerbach and Freud. Then there is the philosophical overcoming of revelation in Schelling and ultimately in Hegel, where a genuine divine-human encounter is transformed into an expressive monism and religion is superseded by philosophy. Finally, there is the existential, historical challenge of an evil unprecedented and radical, the evil of the Holocaust and the Nazi death camps. Throughout his career, in the face of each wave of attack, Fackenheim held firm to the banner of revelation and defended it philosophically - early on as the possibility of a fundamental commitment that is no more an act of sheer faith than are the secularism or naturalism that denied it, later as a possible and even necessary response to the deepest vector of Nazi evil and hence as an expression of hope.

The final theme that pervades Fackenheim's career is a life-long reflection on the complex relationships between thought and life. It is this issue that leads him to Hegel. If any modern philosopher succeeded in articulating how reason and thought, while doing justice to all of history and life, still tame them, it was Hegel. If Hegel failed, perhaps the project cannot succeed. Perhaps, ultimately, life is intractable to thought; perhaps thought must unavoidably go to school with life.

As Fackenheim, in 1966 and after, makes the important, even heroic decision to confront the Nazi Holocaust in all its darkness and its horror, the interdependence of thought and life emerges as central to his thinking (see Holocaust, the). In the essays of 1967 and 1968 Fackenheim's analysis proceeds this way. The thinker, whether philosopher, theologian, historian, or social theorist, confronts Naziism and the death camps with the desire to understand. This desire is quite natural, an expression of aspiration to transcendence that is characteristic of all thought. But probity requires a sense of unease and even humility. The cognitive capacity is paralyzed by the

enormity of the event; what can thought do? It can recognize that meaning and purpose are one thing, response another. The elicitation of meaning here may be impossible. But the response is unavoidable. Hence the thinker, seeking guidance, comes to the realization that real, living Jews have all along been responding in their own ways. In order to understand how one ought to respond and why, the thinker turns to actual response and engages in a 'transcendental' analysis of what makes such response necessary and possible. It is this analysis that leads to Fackenheim's momentous and famous conclusion - that for Jews, whether religious or non-religious, the Divine Commanding Voice was present at Auschwitz and that the imperative which it 'spoke' (and still speaks) was a commandment to resist Nazi purposes, not to give Hitler posthumous victories. This command becomes a means of identifying the ground and content of the necessity for contemporary Jewish existence.

But if authentic post-Holocaust existence - here, Jewish existence - is necessary, is it possible? In the essays of 1967-8, Fackenheim had relied on the Kantian conviction that ought implies can. Paralleling this is the neo-orthodox faith that a God who commands at the same time graciously gives the freedom to respond. By the late 1970s and early 1980s, if not before, these strategies had come to seem inadequate. Indeed, they seemed to belittle the heroism of those who had resisted, as well as the grim courage of those who had not. In the central sections of *To Mend the World* (1982) Fackenheim attempts to rectify the fault. Thought, he acknowledges, tries to comprehend the evil, the pain, the horror, the agency, but as it moves from victim to victim and from agent to agent it acknowledges its own inadequacy. As it tries to grasp why the perpetrators of genocide committed their many crimes, thought fails and fails again until, in a shocking resolution, it grasps the death camps as a whole that is greater than its parts, a whole of horror, a world of evil, and thought is surprised. But the surprise is not neutral; it is recognition, amazement, and horrified recoil, all at once, and while it contains a kind of cognitive grasp, it registers as well a compulsion to oppose. Fackenheim finds this conjunction, this attitude, realized in the actions of some who lived that recognition and that opposition, victims who at the moment of truth resisted and tell us how their resistance was born out of a recognition of the evil, its intent, and the sense of obligation that they felt. In this way, an ontological possibility is grounded in an ontic reality, and in this way too theory and praxis, realized in the event itself as a synthetic whole, lead to action. The theory is incomplete without the praxis, the praxis impossible without the theory.

Facts

The existence and nature of facts is disputed. In ordinary language we often speak of facts ('that's a fact') but it is hard to take such talk seriously since it can be paraphrased away. It is better to argue for the existence of facts on the basis of three connected theoretical roles for facts. First, facts as the referents of true sentences: 'the cat sat on the mat', if true, refers to the fact that the cat sat on the mat. Second, facts as the truth-makers of true sentences: the fact that the cat sat on the mat is what makes 'the cat sat on the mat' true. Third, facts as causal relata, related in such sentences as 'Caesar died because Brutus stabbed him'. The so-called 'slingshot' argument aims to show that these roles are misconceived.

1 Roles for facts

We often speak of facts in ordinary discourse. For example, we append 'the fact' to an indirect sentential clause in sentences such as 'Smith was surprised at the fact that Brown's wife left him'. It is controversial whether this talk of facts is to be taken at face value since the apparent commitment to facts disappears under analysis, becoming 'Smith heard with surprise that Brown's wife left him. Brown's wife left him', in which no mention is made of any fact. Other ordinary talk of facts is also subject to paraphrase: 'It is a fact that *p*' is equivalent to 'It is true that *p*', 'That is a fact' is equivalent to 'That is true'. This last style of paraphrase has been taken in two ways: either as showing that facts do not exist, or that they exist but can be identified with the true bearers of truth-values. Following the second course, the bearers of truth-values are commonly taken to be propositions, that is, the meanings of sentences, and facts are then identified with true propositions.

Rather than squeeze ontological juice from ordinary language, we can argue for the existence of facts on the basis of theoretical demands. First, there is a role for facts within semantic theory, as the worldly referents of true sentences. So a true sentence such as 'The cat sat on the mat' refers to the fact that the cat sat on the mat, sometimes called the situation or state of affairs of the cat sitting on the mat.

A related second role for facts lies within a correspondence theory of truth (see Truth, correspondence theory of). The unworkable correspondence theory of logical atomism, in which correspondence consists in a structural isomorphism between a true atomic sentence and the fact to which it corresponds, is replaced with a truth-maker principle of the form 'every true sentence has a truth-maker' (see Logical atomism). This principle retains the doctrine that the world is independent of linguistic description and must be a certain way for a given sentence to be true of it. The intuitive idea is that a truth-maker grounds the truth of a sentence, where the grounding can be spelled out in a modal fashion: entity *E* is a truth-maker for the sentence *S* just in case necessarily, if *E* exists, then *S* is true. Facts are introduced as the required truth-makers. Neither the particular cat nor the property of sitting on the mat makes 'The cat sat on the mat' true; each might exist even if the sentence is false. But the fact that the cat sat on the mat, consisting of the cat instantiating the property of sitting on the mat, will do the job. Facts as worldly referents or truth-makers of true sentences are best conceived as composite entities, having particulars and properties or relations as constituents, and as themselves parts of the actual world, unlike true propositions which belong to the abstract and other-worldly realm of sense.

Composite worldly facts may play a third role as causal relata (see Causation §6). One way of reporting singular causation uses the sentential connective 'because' (as in 'Caesar died because Brutus stabbed him'), which is true only if the flanking sentences are true. And if the truth-maker principle is right, these sentences need facts as truth-makers, and so the original sentence can be understood as reporting a causal relation between these facts. This account of causal relata has been criticized by Davidson (1967) using the so-called slingshot argument.

2 The slingshot argument

The aim of the slingshot argument is to show that a causal 'because' would have to be truth-functional: that is, the truth-value of a sentence containing the causal 'because' is preserved if one of the sentences flanking the 'because' is replaced by another which shares its truth-value. But it cannot be truth-functional, so the assumption that there is a causal 'because' must be rejected (see Davidson, D.).

In more detail, suppose we are given a true sentence featuring the purported causal 'because': for example, 'Caesar died because Brutus stabbed Caesar'. The idea of the slingshot is to show that this sentence entails a sentence such

as ‘Caesar died because Caesar had a big nose’, which differs from the first only in that a true sentence is substituted for a true sentence flanking the ‘because’. So we have reached the absurd result that the causal ‘because’ is truth-functional.

The steps of the argument are licensed by two premises: that a necessarily equivalent sentence can be substituted for a sentence flanking the ‘because’ without change of truth-value; and that a co-referential singular term can be substituted for a singular term occurring in one of the flanking sentences without change of truth-value. Here is one way to construct a slingshot argument.

(1) Caesar died because Brutus stabbed Caesar.
(2) Caesar died because { x: x is a natural number and Brutus stabbed Caesar}= { x: x is a natural number}.
(3) Caesar died because { x: x is a natural number and Caesar had a big nose}= { x: x is a natural number}.
(4) Caesar died because Caesar had a big nose.

The move from (1) to (2) is justified by the first premise. The singular term ‘{ x: x is a natural number and Brutus stabbed Caesar}’ names the set which contains every object to which the predicate ‘… is a natural number and Brutus stabbed Caesar’ applies; similarly for ‘{ x: x is a natural number}’. So ‘Brutus stabbed Caesar’ is necessarily equivalent to ‘{ x: x is a natural number and Brutus stabbed Caesar}= { x: x is a natural number}’.

The move from (2) to (3) is justified by the second premise. We replace the singular term ‘{ x: x is a natural number and Brutus stabbed Caesar}’ with the co-referential ‘{ x: x is a natural number and Caesar had a big nose}’; these are guaranteed to be co-referential given that ‘Brutus stabbed Caesar’ and ‘Caesar had a big nose’ have the same truth-value. The move from (3) to (4) is justified by the first premise and the fact that ‘{ x: x is a natural number and Caesar had a big nose}= { x: x is a natural number}’ and ‘Caesar had a big nose’ are necessarily equivalent.

We have thus shown that a causal ‘because’ would have to be truth-functional. But it cannot be, so there is no such ‘because’. The slingshot argument is valid, so at least one of the premises must be rejected if facts are to be causal relata. Indeed the slingshot argument also threatens facts in their roles as referents of true sentences and truth-makers for true sentences. For the argument can be used to establish the truth-functionality of ‘sentence *S* refers to the fact that *P*’ and ‘sentence *S* is made true by the fact that *P*’, by operating on the sentence following ‘the fact that’. This yields the undesirable result that a true sentence refers to and is made true by any fact. The slingshot argument cannot be dismissed as logical trickery, for it exposes a critical lacuna in the theory of composite facts. Any motivated criticism of the argument must rely on an account of the identity conditions of facts, and these remain undecided.

Fact/value distinction

According to proponents of the fact/value distinction, no states of affairs in the world can be said to be values, and evaluative judgments are best understood not to be pure statements of fact. The distinction was important in twentieth-century ethics, and debate continues about the metaphysical status of value, the epistemology of value, and the best characterization of value-judgments.

A fact is an actual state of affairs (see Facts). A value is either something good (pleasure, for example), or a belief that something is good (to say that pleasure is one of my values is to say that I believe pleasure to be good) (see Values). The fact/value distinction was of great importance in twentieth-century moral philosophy, a distinction being drawn between actual states of affairs and values in both senses (each sense not always being clearly distinguished from the other).

On one version of the fact/value distinction, there are no values 'in the world'. John Mackie (1977), for example, argued that such items were too peculiar to be fitted into any decent metaphysics or epistemology, and that the nonexistence of values was the best way to explain disagreements in evaluations. According to existentialist ethics, the non-factuality of value leaves us in a position of radical freedom to choose (see Existentialist ethics §§1-2).

The distinction understood as concerning evaluations suggests evaluations are not pure attempts to state facts. One famous and influential version of this view is that of Hume (1739/40), who claimed that 'ought' conclusions do not follow logically from 'is' statements (see Hume. D. §4; Logic of ethical discourse §§1-3). So if you claim successfully that something ought to be done (this may be one of your values) on the basis of an argument apparently referring only to facts, it must be the case that one of your 'factual' statements involves a covert 'ought'.

This version of the fact/value distinction, allied to a narrow conception of what can count as a factual statement, has been of great importance. If facts are, for example, restricted to purely neutral descriptions, such as those found in natural science, moral judgments may be seen as other than fact-stating. (It has been argued by some that science itself is an evaluative enterprise, so that the fact/value distinction is spurious - see Analytic ethics §2.) Words such as 'good' or 'right' can then be claimed to have special, non-descriptive roles. According to emotivism, to claim that X is good is to express a pro-attitude towards it, and perhaps to encourage others to adopt that attitude; according to prescriptivism, the claim is to be understood as imperatival (see Emotivism; Prescriptivism). On such views, certain words, such as 'courageous' for example, may have some factual content; but this can always be distinguished, at least conceptually, from the evaluative content.

Those who have claimed that values are part of the world and that evaluations are fact-stating include advocates of moral realism (see Moral realism). This comes in at least two varieties. Ethical naturalism states that values are natural facts, 'natural' meaning that such facts are to be identified with, or seen as constituted by, facts open to investigation by natural science. Ethical non-naturalism sees values as facts *sui generis*, any attempt to identify them with natural facts being to commit what G.E. Moore (1903) called the 'naturalistic fallacy' (see Naturalism in ethics; Moore, G.E. §1).

Faith

Faith became a topic of discussion in the Western philosophical tradition on account of its prominence in the New Testament, where the having or taking up of faith is often urged by writers. The New Testament itself echoes both Hellenistic concepts of faith and older biblical traditions, specifically that of Abraham in the Book of Genesis.

The subsequent attention of philosophers has been focused primarily on three topics: the nature of faith, the connection between God's goodness and human responsibility, and the relation of faith to reason. Discussions on the nature of faith, from Aquinas to Tillich, have tried to examine the subject in terms of whether it is a particular form of knowledge, virtue, trust and so on. Regarding divine goodness, the argument has primarily focused on the relationship between faith and free will, and whether lack of faith is the responsibility of the individual or of God. Concerning the relation between faith and reason, there are two quite separate issues: the relation of faith to theorizing, and the rationality of faith. Aquinas in particular argued that faith is a necessary prerequisite for reasoning and intellectual activity, while later, John Locke explored the relationship between faith, reason and rationality, and concluded that faith can be reached through reason. This latter viewpoint was later heavily criticized by Wittgenstein and his followers.

1 The New Testament background

In the course of everyday life we speak of persons as having faith in one thing and another - in themselves, in other persons, in causes, in the ability of themselves or others to carry out some project, and so forth. One can imagine some philosopher undertaking, in disinterested fashion, to uncover the nature and role in human life of this phenomenon of having faith; and others then taking up the topic in response to his discussion. There have in fact been a few such discussions. But that is not how faith became a prominent topic of discussion in Western philosophy. It became that because of its prominence in the New Testament; more precisely, because of the prominence the New Testament gives to faith in its description of the mode of life that it advocates. The context is, of course, that the New Testament belongs to the canon of the Christian Church and that Christianity has been powerfully formative of philosophy in the West.

Various writers of the New Testament record Jesus as having urged his hearers to take up the stance of faith. Likewise, those and other New Testament writers urge their own readers to take up this stance. Indeed, they urge their readers to take it up towards Jesus himself. It is clear that when the writers urged this on their readers, and when Jesus urged it on his hearers, they and he saw themselves as doing so on behalf of God.

Sometimes when the New Testament writers represent God as requiring faith of us, they are thinking of faith as one among other things that God requires of us. Faith is then one among other 'virtues'. Paul, in the famous thirteenth chapter of his first letter to the Christians in Corinth, urges on his readers hope and charity along with faith; he concludes that of the three, charity is greatest - on the ground that whereas in the New Age there will no longer be any need for faith and hope, the relevance of charity will abide forever. In other passages, however, the New Testament writers appear to use 'faith' to refer to that total stance towards God to which, on behalf of God, they call us. Then faith in things not seen, hope and charity are three of the requisite *manifestations* of faith. As Rudolf Bultmann remarks, 'In Primitive Christianity, *pistis* became the leading term for the relation of man to God' (1968: 205).

Bultmann observes that in both classical and Hellenistic Greek, the root meaning of *pistis* and its grammatical variants is 'trust' (reliance, belief in, confidence). The objects of *pisteuein* are characteristically such things as contracts and oaths, laws, armaments and persons. Likewise the words of a person can be the object of trust, in which case the sense of *pisteuein* shades towards that of our 'believe'. And sometimes, not surprisingly, *pisteuein* has the nuance of 'to obey'.

In the New Testament as well, the root meaning of the term, when used for that comprehensive stance towards God to which God calls us, is 'trust'. That is especially clear in the famous discourse on faith in the eleventh chapter of Hebrews. The chapter opens with a crisp definition of faith: 'faith is the *hypostasis* of things hoped for, the *elenchos* of things not seen'. In older translations, *hypostasis* and *elenchos* were translated, literally and straightforwardly, as 'substance' and 'evidence' respectively. The authors of the Revised Standard Version, in

recognition of the fact that both words are here being used eccentrically, translate the passage as 'the assurance of things hoped for, the conviction of things not seen'. After giving his definition of faith, and indicating its importance by adding that 'by it the men of old received divine approval', the writer cites examples. His first example is a case of 'conviction of things not seen', not of 'assurance of things hoped for': 'By faith we understand that the world was created by the word of God, so that what is seen was made out of things which do not appear'. All the other examples are cases of both. And in each case, the ground of the assured hope is trust in God's promise to save and bless. It was on account of hope thus grounded that men and women of old 'received divine approval'.

Not only has the Western intellectual tradition been influenced by this general picture of faith and its proper role in human life, but some of the specifics of the New Testament discussion have been influential as well. That is especially true for the discussion of faith in Paul's letter to the Roman Christians. The topic in hand is how to understand theologically the relation of the Christian Church, with its mixture of Jews and Gentiles, to the people of Israel, given that in Genesis it says that God's covenant was with Abraham and all his descendants. The issue was of intense existential concern to Paul, since he was both ethnically Jewish and a Christian. A corollary of the theological issue was the practical issue of whether Christians should be required to follow the ritual practices of Judaism.

The first move in Paul's solution is to refer to Genesis 15: 3, where it says, using Paul's near-paraphrase, that 'Abraham believed God, and it was reckoned to him as righteousness' (Romans 4: 3). From this, along with certain ancillary considerations, Paul draws two conclusions. First, that the divine promise (covenant) is not with those who are descendants of Abraham 'after the flesh' but with those who are descendants of Abraham 'according to the Spirit' - that is to say, not with those who happen to be ethnically Jewish but with those who share Abraham's faith in God and God's promises. Though Paul never offers a definition of faith in the manner of the writer of the book of Hebrews, it is clear that for him, too, trusting in the promises of God is the core, if not the whole, of what he has in mind. The second conclusion Paul draws is that what makes persons pleasing to God is not their performance of some array of ethical and ritual 'works', but simply faith. In the language Paul uses, we are 'justified by faith'. To suppose that one's performance of certain ethical and ritual 'works' would make one just before God would be to suppose that one could achieve that status on one's own — that one could earn it. But we cannot earn it, since we all inevitably in one way or another fail to perform the full panoply of 'works' prescribed in the manner prescribed. Yet Abraham was declared to be righteous before God - that is, just (justified). It follows that having the status of being just before God is a gift on God's part, a status God accords one - on the ground of one's faith. If we are not to fall into contradictions, we must also then understand faith itself as a gift of God, rather than as a 'work' which earns the status of being righteous (justified) before God.

2 The nature of faith

The philosophical discussions of faith almost all fall under one or the other of three headings. In the first place, there is a long history of discussions on the nature of faith. Of what genus is faith a species? Is it a species of believing propositions on say-so? Is it a species of loyalty to some person or cause? Is it a species of trusting someone? Is it a species of believing what someone has promised? Is it a species of 'concern'? Is it a virtue of a certain sort? Is it a species of knowledge? If so, of what sort: *agnitio* (recognition, acknowledgement), *cognitio*, or what? An exceptionally fine example of a philosophical discussion concerning the nature of faith is that by Thomas Aquinas (§14) in *Summa theologiae* IIaIIae, qq.1-7.

The disputes which have arisen among those who propound different analyses of faith have no doubt often had a large component of purely verbal disagreement; if one looks beneath the surface, however, usually one will find a great deal more at stake than just how the word 'faith' should be used. What is customarily at stake is how to understand the fundamental character of a person's proper relation to God; what is often also at stake is the nature of God and of the human being. To give an example: the twentieth-century German-American theologian Paul Tillich (§4) argued that faith is 'ultimate concern'. That proposal was in good measure motivated by Tillich's traditional view that faith is the core of a person's proper relation to God, combined with his very nontraditional conviction that God is the impersonal 'Ground of Being'. The latter conviction made it impossible for him to think of faith as trusting in God's promises - an impersonal entity cannot make promises. Another example: there was a wide-ranging and highly diffuse dispute in the twentieth century as to whether faith has propositional content. The

quick way with the dispute would have been to say that on one concept of faith it does, and on another it does not. But once again, what was actually under dispute, in the context of the shared conviction that faith constitutes the fundamental character of the Christian life, was the nature of divine revelation. Those who held out for faith as having propositional content were of the view that God reveals truths, and that faith consists in part in accepting those truths. Those who held that faith does not have propositional content were of the view that divine revelation consists simply in God manifesting God's self, and that propositions enter the picture only when we human beings interpret the divine self-manifestation. Many other examples could be cited to make the same point: for example, the dispute between the Reformers, who insisted that faith at bottom is *fiducia* (belief *in*), and their medieval opponents, who customarily defined faith as *fides* (belief *that*).

3 Faith, volition and responsibility

Paul's theology of faith in his letter to the Roman Christians has spawned an enormous quantity of theological reflections and controversies. These - the second major type of discussion on faith - have repeatedly spilled over into philosophy. The reason is obvious. Paul interpreted Judaism as a religion of 'works righteousness'. That is to say, he interpreted Judaism as holding that the satisfactory performance of prescribed ethical and ritual 'works' would earn one the status of being righteous (justified) before God. To forestall Christianity becoming Judaism under another guise, with the 'work' that earns justification now being faith, he went on to argue that faith itself is not a 'work' of the person, in which that person can 'glory', but a 'work' of God. Some of the questions this picture poses are subtle; others are obvious. If faith is entirely a gift of God and not a 'work' of the human being, how can anyone other than God rightly be held accountable for a given human being's lack of faith? How can it be just of God to punish a person for lacking faith? Indeed, how can it be just of God to grant it to some and not to others - since presumably the gift of faith itself can no more be earned than can the status of being justified before God? If faith is a good, how can it be good of God to withhold it from certain human beings? To say that the Pauline view posed profound issues of responsibility, free agency, and justice would be to understate the matter. It can scarcely be doubted that the depth of the discussion of these issues in the philosophical tradition of the West is in good measure due to the Pauline inheritance.

4 Faith and reason: the relation of faith to theorizing

The bulk of the remaining discussions of faith, in the philosophical tradition of the West, have been concerned with faith and reason, to use the traditional nomenclature. The nomenclature in fact covers issues of two quite different sorts: the role of faith in theorizing, and the rationality of faith itself.

Issues surrounding the role of faith in theorizing arose out of the confluence between the Bible on the one hand and the texts of classical Greek philosophy on the other. Both Plato and Aristotle held that the ideal human life is the life devoted to theorizing. Though their understanding of theorizing was different in various ways, both regarded it as the acquisition of knowledge, *episteme*, this being understood as awareness or insight; and Plato especially was emphatic in his insistence that the acquisition of *episteme* requires turning away from opinion or belief (*doxa*). Almost everybody in the Christian tradition of late antiquity and the Middle Ages agreed with the classical Greeks that rational insight is a human ideal. Yet none of them thought of faith as *episteme* - or, to use the Latin, *scientia*; all were vividly aware of Paul's statement, in 1 Corinthians 13, that 'now we see in a mirror dimly, but then face to face. Now I know in part; then I shall understand fully'. Hence the problem: as Christians they could not forswear faith, nor regard it as unimportant. Yet, as inheritors of the Greek tradition, they found themselves incapable of renouncing the ideal of rational insight into reality. The 'faith and reason' problem of late antiquity and the Middle Ages was the problem of how to resolve this tension.

Rather than offering at this point a rapid taxonomy of the various attempts at resolution, the main contours of a representative and influential formulation - that of Thomas Aquinas (§11) - will be sketched. Since the deepest happiness of a rational being is found in, and to be derived from, rational activity of the noblest sort, and since God is the one who, above all, is worth our being in rational contact with, our deepest happiness is to be achieved by gaining rational, intellectual contact with God. In general, it is not just the *activity* of exercising reason that gives us happiness, but the *love* of the object known, which is the intrinsic accompaniment of achieving the goal of the activity - namely, coming to know.

One way of gaining intellectual contact with God is by the practice of Aristotelian *scientia*: one starts from

propositions which some rational being has seen to be true, and then proceeds to deduce consequences. In the ideal case, one's premises are propositions that one has oneself seen to be true. Given our human limitations, however, that is often not possible. *Scientia* in its actuality is a communitarian enterprise in which one practitioner often takes it on the say-so of another that they, the latter, have constructed a demonstration of *P* starting from propositions which they personally saw to be true, and in which the first practitioner then takes *P* as a premise for their own work, without trying to prove it independently for themselves. It was Aquinas' conviction that it is possible to prove certain things about God in the ideal fashion; it is possible to construct a natural theology - a *scientia* of God (see Natural philosophy, medieval §§3, 7).

This *scientia* has its limitations, however, especially when assessed by reference to the happiness it contributes to human life. Prominent among the deficiencies, though by no means exhaustive of them, is the fact that, relative to the fullness of God's reality, there is not very much that one can prove about God. Natural theology, as Aquinas saw and practised it, was as subtle and complex in its argumentation and as rich in its results as any other natural scientific enterprise; yet, when one surveys the whole, one notices that nowhere does it yield knowledge of the nature (essence) of God. All that is provable is various relations of God to other things, various consequences of God's activity, and various things that God is not.

Now suppose we understand faith as belonging to the genus of 'believing something on someone's say-so' - specifically, on God's say-so. Faith thus understood also puts us in rational, intellectual contact with God. And when compared to natural theology, it proves advantageous in a number of ways. Prominent among them is the fact that the content of faith extends, at various points, beyond the reach of natural theology; belief that God is trinitarian in nature is an example. On the other hand, there is one serious and undeniable deficiency in faith when compared to natural theology. Whereas the practitioner of natural theology comes to 'see' various things to be true of God, the believer is confined to the inferior mental state of believing things about God on say-so. It is indeed God's say-so; and that makes faith more than mere opinion. Though like opinion in being belief, faith is unlike opinion in being utterly reliable belief, since God is the one believed. None the less, there is no gainsaying the fact that the mental act of 'seeing' a proposition to be true is distinctly better than that of believing it on say-so. It follows that even for a believer there is an advantage in the pursuit of natural theology - given that the believer in question has the time, the intelligence and the training necessary. By the practice of natural theology, the believer 'transmutes' that mode of intellectual contact which they have with regard to various propositions about God, from believing them on say-so to 'seeing' them to be true.

In this precise way, Aquinas would be happy to affirm the Augustinian formula, 'faith seeking understanding' (*fides quaerens intellectum*). He would, in his own way, also be willing to affirm Augustine's other formula, bequeathed to him by Clement of Alexandria, 'I believe in order that I may know' (*credo ut intelligam*). Augustine (§11) not only held that believers should strive to understand those things about God which they already believe, but also, conversely, that a condition of their coming to understand those things is that first they believe them. Augustine's thought was that faith is intertwined with love; and that there is no hope of attaining genuine understanding of God until one loves God. The theme is picked up and expressed in plaintive language by Anselm in the opening pages of his *Proslogion*, where he says that 'the smoke of our wrongdoing' will prohibit us from knowledge of God until that smoke is dissipated by faith. And it is picked up by Aquinas in his teaching that faith and charity are prerequisite for the achievement of such intellectual states as *scientia* and *sapientia* (wisdom).

5 Faith and reason: the rationality of faith

What strikes us in reading Aquinas and other medieval thinkers is that virtually no attention is paid to the question whether faith is itself rational. That question - the other 'faith and reason' topic - first became a matter of concern in the early Enlightenment. Again, rather than attempting a rapid taxonomy of positions held, it will be useful to develop the thought of a representative and influential figure - John Locke (§7).

Locke was living at a time when the traditional medieval view, that the great bulk of the texts bequeathed us together contain a unified body of highly articulate wisdom on moral, religious and philosophical matters, no longer seemed plausible. The textual tradition was now seen as fractured into incompatible components. Furthermore, though the Aristotelian concept of *scientia* remained part of Locke's conceptual repertoire, he himself was of the view that human knowledge in general, and *scientia* in particular, comes to very little. Thus it was that the main question to which Locke addressed himself was this: how should opinion (belief, *doxa*) be

regulated? His proposal was that on those matters where we are obliged to do our best to find out the truth of the matter, we ought to employ the following practice: first, collect satisfactory evidence concerning the truth or falsity of the proposition in question, this evidence consisting of things of which one is certain because one ‘sees’ them to be true; then determine the probability of the proposition in question on that evidence; and then believe or disbelieve the proposition with a firmness proportioned to its probability on that evidence. Locke believed that every normal adult is obliged to do their best on matters of religion - hence, to employ his proposed method on such matters. And since it was his view that no substantive propositions about God can be ‘seen’ to be true, it followed straightforwardly that he was an ‘evidentialist’ concerning theistic belief. One is entitled to believe things about God only if one believes them on propositional evidence. Evidentialism concerning theistic belief has been a prominent position in the West ever since Locke.

Locke’s own concept of faith was exactly the same as Aquinas’: faith is believing things on God’s say-so. Locke did not, however, follow Aquinas in holding that faith, thus understood, is a thing between knowledge and opinion; faith is just a species of opinion. Even more importantly, Locke differed from Aquinas in his emphatic insistence that it is irresponsible to believe something on the ground that God has said or revealed it unless one has good reason, of the indicated sort, for the assumption that God has indeed said or revealed it. Locke himself was of the view that only the occurrence of miracles provides good evidence for divine speech or revelation. In summary: believing something on God’s say-so is responsible only if one has first established in the specified way that there indeed exists a God who is capable of speaking or revealing, and then established, secondly, that there is good evidence of the specified sort for the conclusion that God has said that particular thing.

The way in which Locke connected reason, responsibility and faith has proved enormously influential in the modern world. A great many believers have attempted to meet the Lockean requirement for responsible faith by a combination of collecting evidence of the requisite sort and narrowing the scope of their faith until it contains nothing that the evidence does not justify. A great many nonbelievers have tried to show that the attempts all fail - and that faith is accordingly irresponsible. And a helpful way to look at the project of the Oxford philosopher Richard Swinburne is to look at it as a rigorous and far-ranging attempt to resuscitate the Lockean project in the twentieth century (see Swinburne 1984).

In recent years, however, Locke’s epistemology of religious belief has itself come under persistent attack. Wittgensteinian philosophers of religion, represented especially by D.Z. Phillips (1971, 1976), have argued that religion has its own unique criteria for acceptable belief, and that the flaw in Locke’s argument is that he attempts to impose criteria of acceptability on religious belief which are alien thereto. By contrast, the so-called ‘Reformed epistemologists’ - Alston, Plantinga and Wolterstorff being prominent representatives - while vigorously affirming the propriety of formulating a general epistemology and working at doing so, have gone on to contend that Locke’s foundationalist epistemology as a whole is seriously flawed; and that, in particular, it is often the case that a person who believes some theistic proposition immediately (or basically - that is, not on the basis of propositional evidence) is entirely within their rights in so doing. It is Locke’s universalizing insistence on the need for propositional evidence concerning religious beliefs that is misguided (see Religion and epistemology).

It should be noted that neither the Wittgensteinians nor the Reformed epistemologists espouse the view that the rationality of faith is irrelevant to whether or not it is acceptable to embrace it. That position has traditionally gone under the name of ‘fideism’, and such thinkers as Tertullian, William of Ockham (§9), Pierre Bayle (§1), Søren Kierkegaard (§§4-5) and Leo Shestov (§§3-4) have regularly been classified as fideists. However, when one digs into the thought of the five thinkers mentioned on the topic of faith and reason, one not only finds it to be in each case subtle, and the various positions taken diverse, one also becomes less and less convinced of the propriety of describing any of them as a defender of irrationality in matters of faith. The difficulty lies in good measure in the protean character of our word ‘rational’. If one accepts the Lockean paradigm of rationality, then the Wittgensteinians and the Reformed epistemologists will also be regarded as defenders of irrationality in matters of faith - a characterization which both parties themselves, however, would firmly reject. In short, interwoven with different positions on the rationality of faith are different positions on the nature of rationality - as, indeed, on the nature of faith.

Fallacies

Fallacies are common types of arguments that have a strong tendency to go badly wrong, or to be used as deceptive tricks when two parties reason together. In some instances they are simply careless errors in thinking, while in other cases they are techniques of argumentation used by one arguer more or less deliberately to try to fool another into accepting a false conclusion. Fallacies have been described in logic textbooks since the time of Aristotle; their study, long neglected, has begun to be revived in recent years, as its practical importance in natural language reasoning has become apparent.

Many fallacies have been recognized, but some major ones that are unquestionably very common and influential in familiar thinking on all subjects have been emphasized in logic textbooks and manuals since the time of Aristotle - see Hamblin (1970) for a survey of these and their historical background. Fallacies were first systematically studied by Aristotle in his book *De Sophisticis Elenchis (On Sophistical Refutations)* and many of the textbook treatments have basically followed Aristotle's, except that more fallacies have been added along the way. Below, some of the traditionally most important fallacies are briefly characterized.

The '*ad hominem* fallacy' is the use of personal attack to try to undermine or refute a person's argument. Broadly, this takes two forms. The 'abusive *ad hominem*' consists of a direct attack on the arguer's character, and in particular, honesty. The 'circumstantial *ad hominem*' alleges some form of conflict between the arguer's personal circumstances and the argument. For example, it might be the charge that the arguer 'does not practise what he preaches', or that the arguer is biased because of having something to gain financially by advocating the argument in question.

The '*ad verecundiam* fallacy' is the use of appeal to expert opinion to support one's argument in such a way as to take advantage of one's opponent's respect for authority, allowing no room to question the pronouncement of an expert. Appeal to expert opinion is a common, and in principle legitimate, type of argumentation, but one that is easily abused by being pressed too heavily in an argumentative exchange. Experts can be (spectacularly) wrong in some cases, and their views can be misquoted, or otherwise distorted, especially when they use technical language.

The '*ad ignorantiam* fallacy' is the exploitation of ignorance (lack of knowledge) by one party in a dialogue to try to shift the burden of proof unjustifiably onto the other party. This type of argument takes two forms: (1) It is not known that proposition *A* is true; therefore *A* is false; (2) it is not known that *A* is false; therefore *A* is true. An example would be: 'This supposed theorem has never in fact been proved to be true, therefore it must be false'. In such a case, it could be that the conjecture has just been very difficult to prove, and no one has succeeded so far, but that somebody will prove it in the future. The fallaciousness of such an argument is indicated by the fact that there is such a thing as an incompleteness proof in logic; a proof that some propositions cannot be proved (see Gödel's Theorems).

The '*ad baculum* fallacy' is the use of threat or, more broadly, scaremongering, to try to exploit the insecurity of one's opponent to get them to accept some proposition, instead of justifying the proposition by good evidence. Instances of the *ad baculum* fallacy often take the form of covert threats, for example, 'I wouldn't say that if I were you - the last person who said it wound up on the bottom of the river wearing cement boots!'

The '*ad misericordiam* fallacy' is the blowing up out of proportion of an appeal to pity to cover up for lack of evidence to support a claim; or to brush aside other considerations that should be given more importance in arriving at a conclusion. There are many instances of quite reasonable arguments based on appeals to compassion or sympathy, but it is easy to blow such emotional appeals out of proportion to the slender weight of evidence that should be attached to them (within a larger evidential picture).

The '*ad populum* fallacy' is committed when an arguer suggests that someone's argument is wrong or unacceptable in so far as it deviates from popular opinion, or the conventionally accepted view. When pursued with rhetorical enthusiasm, this type of argumentation is called 'mob appeal'.

'Begging the question' is a kind of fallacious circular reasoning in which the conclusion is itself required as a premise to support the argument being advanced to justify the conclusion. Many cases of this type of fallacy are

disguised by being quite complex arguments - see Walton (1991) - but a simple case would be the following argument: someone asked to prove that God is benevolent replies, ‘God has all the virtues, therefore God is benevolent.’ Since benevolence is presumably a virtue, the premise requires the prior assumption that God is benevolent.

‘Equivocation’ is the fallacy whereby an argument contains an ambiguous word or phrase that means one thing in one premise, but something different in another premise or in the conclusion. As a consequence of this shift of meaning, one may be fooled into thinking one has been presented with a single argument, which looks pretty good.

The ‘straw man fallacy’ is committed when one arguer misrepresents another’s position to make it appear less plausible than it really is, in order more easily to criticize or refute it. For example, an environmentalist position may be exaggerated by saying, ‘They are trying to make this country a paradise on earth, by barring all industrial development. They will cause all of us to become unemployed.’

The ‘fallacy of affirming the consequent’ appears to be valid because of its superficial similarity to the valid form of argument *modus ponens*. An example of this valid form would be: ‘If it is raining, the streets are wet. It is raining. Therefore, the streets are wet.’ The comparable argument in the form of affirming the consequent may have the superficial appearance of also being valid: ‘If it is raining, the streets are wet. The streets are wet. Therefore, it is raining.’ (But maybe the streets are wet because a water main has burst.) It is perhaps because of our tendency to reverse the first premise in some instances that we can be deceived by this kind of fallacious reasoning.

Fallibilism

Fallibilism is a philosophical doctrine regarding natural science, most closely associated with Charles Sanders Peirce, which maintains that our scientific knowledge claims are invariably vulnerable and may turn out to be false. Scientific theories cannot be asserted as true categorically, but only as having some probability of being true. Fallibilists insist on our inability to attain the final and definitive truth regarding the theoretical concerns of natural science - in particular at the level of theoretical physics. At any rate, at this level of generality and precision each of our accepted beliefs may turn out to be false, and many of them will. Fallibilism does not insist on the falsity of our scientific claims but rather on their tentativity as inevitable estimates: it does not hold that knowledge is unavailable here, but rather that it is always provisional.

1 The fallibilist perspective

Fallibilism is the view that we have no assurance that our scientific theories or systems are definitely true; they are simply the best we can do here and now. New theoretical knowledge does not just supplement but generally upsets our knowledge-in-hand. A scientific theory or system - like any product of human contrivance be it a house or a knowledge-claim - is ultimately bound to encounter conditions that its constructors did not and could not anticipate and which render its ultimate failure likely. Changed social conditions destabilize social systems; changed physical conditions destabilize physical structures; changed experiential (that is, experimental and observational) conditions - changed scientific technology, if you will - destabilize scientific theories. Rational inquiry links the products our understanding to the experienced conditions of a world in which chance and chaos plays an ineliminable role, so that there will always be new conditions and circumstances that ultimately threaten our rational contrivances. Thomas Kuhn's picture of scientific progress, which envisages a repetitive cycle of periods of normal science punctuated by revolutionary revisions, lends itself naturally to such a construction (see Kuhn, T. §§2-3).

Peirce, the most prominent exponent of fallibilism, has not been alone. Other recent thinkers who have espoused scientific fallibilism include Gaston Bachelard, Rudolf Carnap, Pierre Duhem, and Karl Popper. In antiquity, the mitigated sceptics of the middle academy were the precursors of this position, since they taught that we can never achieve certain knowledge (*epistēmē*) in matters regarding the world's ways, but have to make do with what is merely probable or plausible (*to pithanon*) (see Carneades §4).

2 Grounds for fallibilism

Why should we see all of our claims to knowledge of the world - even our best state-of-the-art scientific theories - as vulnerable? One of the most basic lessons of modern epistemology is that the available observational data underdetermine theories. For observations are always discrete, finite in number, and episodic. They deal in specific information-yielding episodes that occur at particular times and places. Theories, on the other hand, are general and non-finite: they deal in how certain features of a generic sort characterize situations of a certain kind always and everywhere. Accordingly, theories transcend the data and reach beyond them, so that there is always an evidential gap between the claims of a theory and the particular facts that are its supporting data. (The fitting of a continuous curve to discrete data points provides a somewhat oversimplified analogy.) Theories - as Pierre Duhem emphasized - lie beyond the possibility of definitive confirmation by data.

This data-transcendence of all theoretical claims means that there will always be various alternative ways of rounding the data off into generalized theories. The available data themselves can never constrain unique theoretical resolutions. Observed data are finite, possible hypotheses infinite, and the finite cannot constrain the infinite. The concrete realities we experience observationally are always to some extent ambiguous. They always admit, in principle, of alternative theoretical rationalizations. Theorizing without data is futile. But even theorizing on the basis of data involves interpretation, and thus carries in its wake the prospect of ambiguity, diversity and discord. The experiential realities determine and canalize the work of theorizing reason, but they cannot impose altogether unique resolutions upon it. In sum, theories are always informatively underdetermined by data (see Inference to the best explanation; Underdetermination).

There is much in this picture of the cognitive situation that rings true. The fact is that the equilibrium achieved by natural science at *any* given stage of its development is always an unstable one. The subject's history indicates that

scientific theories have a finite life span; they come to be modified or replaced under various innovative pressures, in particular the enhancement of observational and experimental evidence (through improved techniques of experimentation, more powerful means of observation and detection, superior procedures for data-processing, and so on). As C.S. Peirce and, subsequently, Karl Popper have insisted, we must acknowledge an inability to attain the final and definitive truth in the theoretical concerns of natural science - in particular at the level of theoretical physics. Our present science cannot plausibly claim to deliver a definitive picture of physical reality. We would like to think of our science as something safe, solid and reliable. Unfortunately, however, history militates against this comfortable view. In science, new knowledge does not just supplement but generally upsets our knowledge-in-hand.

We learn by empirical inquiry about empirical inquiry, and one of the key things we learn is that at no actual stage does science yield a final and unchanging result. We have no responsible alternative to supposing the imperfection of what we take ourselves to know. (And there is no reason to see the posture of our successors as fundamentally different from our own in this respect.) We occupy the predicament of the 'Preface Paradox' exemplified by the author who apologizes in his preface for those errors that have doubtless made their way into his work, and yet blithely remains committed to all those assertions he makes in the body of the work itself. We know or must presume that (at the synoptic level) there are errors, though we certainly cannot say where and how they arise (see Paradoxes, epistemic §1).

3 Approximation and its problems

To protect scientific realism in the face of the prospect of unending scientific change, it is tempting to adopt Peirce's stratagem of a resort to *convergent approximation*. This calls for envisaging a situation where, with the passage of time, the theories we successively arrive at grow increasingly concordant and their claims less and less differentiated. In the face of such a course of successive changes of ever-diminishing significance, we could proceed to maintain that the world really is not as *present* science claims it to be, but rather is as the ever-more clearly emerging science-in-the-limit claims it to be. The reality of ongoing change is now irrelevant, as with the passage of time the changes matter less and less. We increasingly approximate an essentially stable picture. This prospect is certainly a theoretically possible one. But neither historical experience nor considerations of general principle provide reason to think that it is actually possible.

Any theory of convergence in science, however carefully crafted, will shatter against the *conceptual innovation* that continually brings entirely new, radically different scientific concepts to the fore, carrying in its wake an ongoing wholesale revision of 'established fact'. Investigators of an earlier era not only did not *know* what the half-life of californium was, but they would not have *understood* it even if this fact had been explained to them. The questions we can pose are limited by our conceptual horizons. It did not appear to be a realistic prospect to all those late nineteenth-century physicists who investigated the properties of the luminiferous ether that no such medium for the transmission of light and electromagnetism might exist at all. Ongoing scientific progress is not simply a matter of increasing accuracy by extending the numbers in our otherwise stable descriptions of nature to a few more decimal places. Significant scientific progress is genuinely revolutionary in involving a fundamental change of mind about how things happen in the world. Progress of this calibre is generally a matter not of adding further facts, like filling in a crossword puzzle, but of changing the framework itself. And this blocks the theory of convergence.

Accordingly, we should temper our claims to scientific knowledge with a Cognitive Copernicanism. The original Copernican revolution made the point that there is nothing *ontologically* privileged about our own position in space. The fallibilistic doctrine now at issue effectively holds that there is nothing *cognitively* privileged about our own position in time. A kind of intellectual humility is in order - a diffidence that abstains from the hubris of pretensions to cognitive finality or centrality. Such a position calls for the humbling view that just as we think our predecessors of a hundred years had a fundamentally inadequate grasp on the furniture of the world, so our successors of a hundred years hence will almost certainly take the same view of *our* purported knowledge of things. The facts of epistemic life require us to recognize that, as concerns our scientific understanding of the world, our most secure knowledge is very likely no more than presently acceptable error. Such a view of scientific progress enjoins an even more modest position than Peircean convergentism.

In any convergent process, later is lesser. But since scientific progress on matters of fundamental importance is

generally a matter of replacement rather than mere supplementation, there is no reason to see the later issues of science as lesser issues in the significance of their bearing upon science as a cognitive enterprise - to think that nature will be cooperative in always yielding its most important secrets early on and reserving nothing but the relatively insignificant for later on. The fact is that a very small-scale effect - even one that lies very far out along the extremes of a 'range exploration' in terms of temperature, pressure, velocity, or the like - can force a far-reaching revolution and have a profound impact by way of major theoretical revisions. (Think of special relativity in relation to etherdrift experimentation, or general relativity in relation to the perihelion of Mercury.) Given that natural science progresses mainly by substitutions and replacements that go back to first principles and lead to comprehensive overall revisions of our picture of the phenomena at issue, it seems sensible to say that the shifts across successive scientific 'revolutions' maintain the same level of overall significance - it is neither a convergent nor a divergent process. Thus if we are to be realistic fallibilists we must hold a position more radical than that of Peirce. His approximationism cannot offset the sceptical impetus of fallibilism. There are, however, mitigating circumstances.

4 Scientific versus everyday knowledge

Fallibilists are prepared to concede that the claims of descriptive astronomy or of human anatomy are true enough. But they insist that the frontiers of theorizing are very different. With any sort of estimate, there is always a characteristic trade-off relationship between the evidential *security* of the estimate on the one hand (as determinable on the basis of its probability or degree of acceptability), and its contentual *definiteness* (exactness, detail, precision, and so on) on the other. But technical science forswears the looseness of vague generality: its law claims are strict and unshaded. In making the assertion 'The melting point of lead is $327.5°$,' we mean to assert that *all* (not most) pieces of (pure) lead will unfailingly melt at *exactly* (not somewhere around) this temperature. In technical science we always aim at the maximum of universality, precision, accuracy and exactness. And this commitment to generality and detailed precision renders the claims of science highly vulnerable. We realize that none of the hard claims of present-day frontier natural science will move untouched down the corridors of time.

The interesting fact is that fallibilism is a more plausible doctrine with respect to scientific knowledge than with respect to the less demanding 'knowledge' of everyday life. Ordinary-life generalizations are such as to allow one who asserts (say) that peaches are delicious, to be asserting something like, 'Most people will find the eating of suitably grown and duly matured peaches a rather pleasurable experience'. Such statements have all sorts of implicit safeguards, that can be cashed in through such guarding locutions as 'more or less', 'in ordinary circumstances', 'by and large' and so on. They are thus so well hedged that it is eminently implausible that contentions such as these should be overthrown.

In science, however, we willingly accept greater cognitive risks because we ask much more of the project. Here the objectives are primarily theoretical and governed by the aims of disinterested inquiry. Accordingly, the claims of informativeness - of generality, exactness, and precision - are paramount. We deliberately court risk by aiming at maximal definiteness and thus at maximal informativeness and testability. Aristotle's view that terrestrial science deals with what happens ordinarily and in the normal course of things has long ago been left by the wayside. The theories of modern natural science have little interest in what happens generally or by and large; they seek to transact their explanatory business in terms of strict universality - in terms of what happens always and everywhere and in all kinds of circumstances. We therefore have little choice but to acknowledge the vulnerability of our scientific statements, subject to the operation of the security-definiteness trade-off. Ironically, then, the 'common sense' of everyday life is securer than the more sophisticated claims of frontier science.

This distinction between the rougher but more secure level of 'schoolbook science', as it were, and the more demanding (but destabilizing) level of technical science at the frontiers of research, enables one to hold the realistic view that science does actually describe the real world, while accepting the implications of ongoing change in our scientific view of the world. The point is not that our pursuit of truth in science is futile, but rather that the information we obtain is to be seen as no more (but also no less) than the best available *estimate* of the truth that is available to us in the circumstances. Fallibilism is something very different from nihilistic scepticism.

5 Ethical ramifications of fallibilism

Some philosophers (Peirce included) see fallibilism as having ethical implications. They project an ethics of belief,

according to which we have no right to claim definitive truth for our current scientific claims, a view which they combine with a purported duty for the community of thinkers to pursue inquiry to the greatest extent possible in the circumstances. Accordingly, they insist that the fallibilism of our cognitive endeavours must emphatically *not* be construed as an open invitation to a sceptical abandonment of the scientific enterprise. Instead, it is an incentive to do the very best we can. In human inquiry, the cognitive ideal is correlative with the striving for definitive systematization. And this is an ideal that, like other ideals, is worthy of pursuit despite the fact that we must recognize that its full attainment lies beyond our grasp.

Family, ethics and the

Do obligations to children take priority over filial and other family obligations? Do blood kin have stronger moral claims than relatives acquired through marriage? Whatever their origin, do family obligations take precedence over obligations to friends, neighbours, fellow citizens? Do family moral ties presuppose specific family feeling, love, or loyalty? Is the traditional family of a married, heterosexual couple with biological offspring morally preferable to families formed by adoptive, single, remarried or same-sex parents, or with the help of gamete donors or gestational ('maternal') surrogates? On what grounds may friends, neighbours or government agencies intrude upon 'family privacy'?

To simplify the complexity and diversity of family life, reasoned answers to such questions may stress a single dimension. A metaphysical *approach draws on the commands of a deity or the needs of a nation. A* biological *approach appeals to physical resemblance, blood or genes. An* economic *approach focuses on family property, income, division of work and resources, and inheritance. A related* political *approach attends to power, subordination, and rights within a family, as well as to their regulation by the state. A* psychological *approach takes affection, identification, intimacy, and emotional needs as morally decisive. A* narrative *approach makes recalling and revision of family stories the basis of moral education and the definition of family ties.*

Although mutually compatible, these approaches do each tend to favour particular moral theories.

1 Metaphysical conceptions of families

As in the major religions of Middle Eastern origin, parents may be regarded as recipients of God's gifts of newly created life. As such they are deputized guardians, not creators with powers of life and death over their creatures. Or, parents and children are seen as dutiful representatives of generations of long dead, but still attentive and demanding ancestors. In some versions or secular analogues, it is the nation or race that married couples must preserve and serve through the children they bear and rear. Accordingly, decisions about suitable marriage partners, or family size and comportment are decided by authorities speaking in the name of the transcendental agent or group, not by romantic couples or family-planning individuals.

Each of these theories prompts questions about the existence and moral authority of the metaphysical agent or collective invoked, such as: How can long dead ancestors continue to make demands of service or obedience on the living? How can a racial or national identity require those to whom it is ascribed to marry and procreate within its socially constructed limits? Answers to such questions often suppose that individuals are defined by particular relational properties (for instance, children of God the Father, sons of Erin, descendants of slaves). By contrast, Kantian and Utilitarian moral theories presuppose a metaphysical individualism of persons, each defined by nonrelational capacities for reason, good will, interests, or preferences (see Kantian ethics; Utilitarianism). Accordingly, children are not conceived as belonging to their parents, clan, or God, but as dependent on others for gradual development of their autonomy.

2 Biological conceptions of families

On a biological view, family ties are defined primarily through reproductive and genetic links. We distinguish between 'real' or 'true' mothers and adoptive, 'social' or step-mothers, full brothers and half-brothers, first cousins and distant cousins. Such traditional distinctions are accompanied by different levels of priority within families: the saying that 'blood is thicker than water' (and than diluted blood) indicates that blood kin have greater obligations to one another than to other relatives, but presumably find those greater demands less onerous in virtue of a natural sympathy that sociobiologists attribute to gene-preserving strategies (see Sociobiology).

However enshrined in legal and moral sentiment, this biological-based approach has problems of gradation, derivation and scope. Whatever genetic links or tendencies, do we owe half-sisters less loyal support? Do adoptive parents have more excuse for failing in their parental duties of care and comfort? Do adopted children have less obligation to 'honour' their parents, or more? If the moral gradations set out in such questions are indefensible, it would seem that an appeal to more than Darwinian notions would be needed to bridge Hume's gap between *is* and *ought* (see Logic of ethical discourse §§1-3).

But even if such prescriptive norms for family composition and conduct can be drawn from evolutionary or any other biological theory, there is an issue of scope. Whatever the value ascribed to biological connections, they are only a fraction of the ties by which families are formed and maintained. Biological considerations may govern marital and reproductive choices but have little or no bearing on many other family obligations, such as those of parents to their in-laws, or to one another, or to their children once they have become adult (grandchildren aside). Non-biological bases must be found for these other familial ties.

3 Economic conceptions of families

For many social scientists, a family is a household, a group of cohabitants who stand in various kinds of economic relationships, actual or potential. Kant and other family traditionalists have claimed male heads of family to have property rights in their wives and children (see Property). In many cultures, parents regard early support as an investment that children repay by working in or outside the home, by suitable marriages, and eventual care in old age. Adult children often regard their grandparents and parents as stewards of family assets to be used and distributed with due regard for the next generation (see Future generations, obligations to). So viewed, a family produces, consumes, accumulates and transmits economic goods.

This approach focuses on what for most families are principal sources of distress and dispute, namely, distribution of labour, goods, and economic responsibilities. It also helps expose unexamined divisions of family labour, for example, the unpaid labour of women who maintain the home and care for the young, ill and elderly family members who otherwise would need public services. In some areas of family life, economic assessment of women's traditional work is explicit, for example, in the hiring of substitute home childcare workers or gestational ('maternal') surrogates - practices often criticized for having a financial aspect that subverts the natural affection that ideally motivates the bearing and rearing of children.

Economic analyses are most compatible with utilitarian moral theories: both share the ideal of a quasi-calculus (of costs and benefits, or positive and negative utilities) for reaching principled decisions on actions or policies, for individuals or for groups with disparate interests or preferences (see Utilitarianism; Rational choice theory). In general, however, both approaches seem to ignore or discount a variety of morally relevant factors (fairness, needs, altruistic and selfish motives) that seem important in family matters. Moreover, both seem to presuppose individuals, with clearly distinguishable preferences and interests. But those families that do satisfy this requirement are not likely to have the solidarity, or intimacy, or communal history that other accounts of the family take to be definitive or primary (see Solidarity). Families composed of rational, self-interested, negotiating utility-maximizers seem like temporary roommates, not people who share a life over their lifetimes. This criticism does not, however, count against economic analyses less reliant on a calculus of individual interests.

4 Political conceptions of families

As in society generally, economic relationships reflect and produce within the family differences of power and subordination. Families are political in at least two senses: they are the 'basic units of society' in which social values are inculcated, enforced, or subverted; and they are also mini-realms in which power is distributed and exercised among and over its members. In some political theories, families have been the model for the larger polity, rulers cast as fathers and their subjects as their children.

John Locke (1689) attacked such patriarchy, both political and domestic, limiting the scope and duration of parents' authority over their children. Contemporary egalitarian critics view the traditional family as exploiting gender and age inequalities, as well as fostering unjust disparities of wealth. Some family theorists have found a remedy in Kantian notions of autonomy or in Rawls' 'difference principle', applied to families taken to be part of the basic structure of a society (see Autonomy, ethical; Rawls, J. §1). This principle allows differences in wealth, opportunities, and other 'primary social goods' only to the extent that they make the worst off members better than they would otherwise be.

Some feminist critics think that this principle still allows for traditional gender divisions of family labour (see Feminist political philosophy §5); communitarian critics find it too individualistic to do justice to the shared interests that sustain family life and obligation (see Community and communitarianism). Both types of critic tend to see the notion of individual rights as essentially adversarial, needed only when family feeling and harmony are

failing. On the other hand, family harmony and feeling may depend on the weaker members' confidence that conflicts of interest will be resolved equitably, a confidence that requires explicit recognition and respect of their individual rights of liberty and reciprocity.

5 Psychological conception of families

Neither the political nor the other approaches take much thought for the complex emotions that give families their peculiar fraught unity. In most modern cultures families are supposed to begin in love, or at least the hope of love, and be sustained by the love that grows among its members. Maternal love especially - whether connected with gestation and birth - is taken to be a deep, abiding base for self-sacrificial care and forgiveness (see Feminist ethics §2); brotherly love is supposed to be a model for relationships outside the family. But these emotional stereotypes ignore the variety and complexity of maternal or sibling sentiments.

To correct such sentimental simplicities, there is a growing philosophical literature on various intimate relationships and their emotions from which to draw. And, of course, any philosophically adequate phenomenology of family feeling must draw freely and widely from the world of plays, poetry, and novels in which familial emotional ties, both preserving and abusive, are central.

6 Narrative conceptions of families

Literature aside, families tend to create and recreate their own stories that serve to inspire loyalty, pride and identification with one another and with selected ancestors. By such stories of courageous grandparents, generous uncles, devoted sisters, good and bad in-laws, notions of family honour are defined and family trees are selectively pruned and shaped, thereby setting the moral parameters within which family members are expected to move, even if at odds with wider social mores.

This narrative approach is far from the Kantian conception of morality as based on general principles, applied impersonally across family and cultural boundaries (see Universalism in ethics). For any moral philosopher who insists that moral principles or lists of virtues and vices be derived from or constitute a human nature, to give moral weight to such family stories might seem to endorse a kind of idiosyncratic, asocial moralism without sufficient concern for the role of families in a civic culture. There is, however, nothing inherently asocial in a moral education that appeals to ancestral deeds and family tradition. Family heroes and villains are often remembered for their public as well as their private acts, virtues, and vices. Told and retold with revisions, these family litanies are akin to the common law, or much religious moral pedagogy (see Moral education). Philosophically, this narrative approach to family morality can find a framework in the existentialist ethics of thinkers such as Sartre, de Beauvoir, and Marcel (see Existentialist ethics).

Such literary approaches would favour an ethics of precedent rather than an ethics of principles, not unlike the common law and the teachings of the major Middle Eastern religions.

7 Conclusion

Each approach may yield reasoned answers to some of the various questions a comprehensive ethics of the family would pose. Whether we should expect any single approach to answer all such questions is debatable, especially in cultures for whom 'the family' no longer refers to a single, well-defined and widely-accepted norm. The diversity of families, as well as each family's complexity, may require a plurality of approaches, perhaps even greater than the six sketched here. What we should hope for, perhaps, is not a systematic ethics of the family, but a conceptually enriched capacity for moral reflection on family matters as they arise in context at different stages of our lives.

Fanon, Frantz (1925-61)

Fanon's views (and often various misinterpretations of them) on the nature of colonialism, racism and the role of violence in Third-World revolutions were enormously influential. The main themes of all his writing are the critique of ethnopsychiatry and the Eurocentrism of psychoanalysis, the critique of négritude *and the development of a political philosophy for Third-World liberation.*

Frantz Fanon was born in the French Antilles on the island of Martinique and was educated there and in France. He served in the Free French army during the Second World War, both in north Africa and in Europe. He went on to study medicine and psychiatry at the University of Lyons between 1947 and 1951. In 1953 he was appointed chief of service of the psychiatry department of a hospital in Algeria (which was then still a French territory). He joined the Algerian liberation movement in 1954 and began to work for its underground newspaper El Moudjahid a few years later. His political activities caused him to leave his job, after which he moved to Tunisia where he practised psychiatry from 1957 to 1959. In 1961 he was appointed ambassador to Ghana by the Algerian provisional government. He died of leukaemia in 1961.

1 *Black Skin, White Masks*

Fanon's work is profoundly shaped both by his (largely psychoanalytic) training as a psychiatrist and his response to the work of European ethnopsychiatrists trying to understand the psychology of non-European peoples. But, like all African and Afro-Caribbean intellectuals in the Francophone world in the 1950s, he was also shaped (if only in reaction) by the ideas of the *négritude* movement (see African philosophy, Francophone §4). In his first book *Black Skin, White Masks* (1952), Fanon asserted that 'the black soul is a white man's artefact'. He claimed that the purportedly essential qualities of the negro spirit celebrated by the writers of *négritude* were a European fantasy. Fanon also argued against *négritude* that its assumption of a natural solidarity of all black people in the Caribbean and Africa was a political error; that far from needing to return to an African past, black intellectuals needed to adapt to modern European culture and that the movement had done nothing to change the everyday life of ordinary black people.

Yet even in this work (and more so later) he conceded that *négritude* could play an important role in freeing native intellectuals of dependence on metropolitan culture. This position which combined a critique of the theoretical claims of *négritude* with an account of it as a historically progressive movement, has affinities with Sartre's account of *négritude* in his essay 'Orphée noir' (1948) (see Sartre, J.-P.). Fanon's vehement attack on Sartre is surprising, therefore, in which he says that Sartre has undermined black fervour in his account of *négritude* as the 'minor term' of a dialectical progression from racism to humanism.

In *Black Skin, White Masks* Fanon developed an account of the psychological effects of racism. However, he did not acknowledge that he was referring to a racism that was based on the experiences of the black middle class in the French Caribbean. The dominant colonial culture, he argued, identifies the black skin of the negro with impurity. The Antilleans accept this association and have come to despise themselves. For example, colonial women exhibit their identification with whiteness by attempting neurotically to avoid black men and to get close to (and ultimately cohabit with) white men. This process Fanon dubbed 'lactification'.

This self-contempt manifests itself in other ways, for example, as anxiety in the presence of whites about revealing one's 'natural' negro inferiority; in a pathological hypersensitivity that Fanon dubbed 'affective erethism'; in existential dread and in a neurotic refusal to face up to the fact of one's own blackness. ('Erethism' is a medical word for pathologically irritable tissue: 'affective erethism', by analogy, is pathological irritability of the feelings.) Black children raised within the colonial system where racist cultural assumptions were prevalent can partially resolve the tension between contempt for blackness and their own dark skins by coming to think of themselves, in some sense, as white (hence the 'white masks' of the title). This fantasy can only be maintained away from direct exposure to Europeans: once the Antillean reaches metropolitan France, Fanon says, this illusion is destroyed with consequent damage to the ego.

2 Other works

Fanon's approach in *Black Skin, White Masks* focuses on the problems of identity created for the colonial subject

by colonial racism. In the course of the book he not only develops this account, but also criticizes the alternative accounts of the 'native mind' in the ethnopsychiatry of Octave Mannoni, proposing that his *Prospero and Caliban* (1964) is an apology for colonialism. He argues, too, that psychoanalytic theory (in the Adlerian and Jungian forms he draws on most heavily) requires substantial revision if it is to give an adequate account of the psychological development of non-European peoples.

In *Toward the African Revolution* (1964), Fanon developed an account of the ways in which the colonial system and its ideology over time adapted themselves to the changed economic realities. He argued that colonial racism begins as 'vulgar' racism. The aim of this racism is to prove the inferiority of colonial subjects by appealing to anatomy or physiology and especially to notions of the inferiority of their nervous systems. A later form of 'cultural' racism proposes that it is the culture of the native that is inferior. Fanon argued that the shift from vulgar to cultural racism reflected changes in the economic character of colonialism. As the colonial system developed it created a new class of colonial subjects trained in European methods and who, in collaborating with the colonizer, profited from the colonial system.

The changes associated with the creation of this new colonial class are characterized in *The Wretched of the Earth* (1961) as a transition from 'extractive' to 'consumer' colonialism. Whereas his earlier work had focused on a primary distinction between colonizer and the colonized, Fanon (1961) introduced, for the first time, a class analysis of colonialism which offered a more detailed account of the internal divisions of colonial societies.

In the extractive phase of colonialism there exists a peasantry, a traditional ruling group and a small number of native traders. In the transition from extractive to consumer colonialism a native petty bourgeoisie, a landed bourgeoisie, a proletariat and a lumpen-proletariat develop. However, Fanon rejects a conventional Marxist account of the colonial situation because he believed that the association of whiteness with money and power meant that the ruling class was identified by race, not by its relation to the means of production. Therefore, conventional class analysis and accounts of the role of ideology fail, power relations are crudely fixed and no ideology conceals the reality of the situation (see Marx, K.).

Instead, Fanon offers an account in which the peasantry are the revolutionary class who have escaped the total devastation of the traditional culture that has overtaken the bourgeoisie and the proletariat. Their revolutionary urge derives from their bid for land. Such a bid leads them to reject the colonizers' expropriation of the colonial territory. While Fanon expressed some ambivalence towards the revolutionary ardour of the peasantry, what was seen as his celebration of their revolutionary potential, rooted in their resistance to colonial cultural domination, was taken up by many Third-World intellectuals in the 1960s.

As Fanon died young and his last book was written under great pressure of time, there is no final attempt to bring consistency to the many strands of his work. For example, the psychological analysis of questions of identity begun in *Black Skin, White Masks* is never fully integrated with the increasingly political analysis of later essays and books.

Fardella, Michelangelo (*c*.1646-1718)

Fardella was one of the first and most famous Italian Cartesians. Influenced by Malebranche and Leibniz, he rejected materialism in metaphysics, and endorsed a strongly Augustinian form of Cartesian dualism in philosophy of mind. In mathematics, he popularized Descartes' analytic method. An insufficiently radical thinker, the cultural significance of his work rests on his defence of the Cartesian method against scholasticism.

The Italian Michelangelo Fardella was educated by the Franciscans. Introduced by Giovanni Alfonso Borelli to mathematics and the Galilean method, he soon acquired an everlasting dislike for scholasticism. In Paris (1678-80), he became acquainted with the Cartesian movement and possibly Malebranche, whose writings affected his Augustinianism. He taught in Rome, Modena and Padua (1694-1710), where he was an influential advocate of Cartesianism. Between 1690 and 1714 he corresponded with Leibniz, and published his three major works: *Universae philosophiae systema* (1691), a methodological treatise presenting a critical combination of themes from the Logic of Port-Royal and Descartes; *Universae usualis mathematicae theoria* (1691), a presentation of the various branches of mathematics based on Descartes' method; and *Animae humanae natura ab Augustino detecta* (1698), a long, erudite commentary on Augustine's works, meant to demonstrate that the mind or soul is incorporeal and eternal (see Augustine §§5-6). In 1710 he became theologian and mathematician to Charles III in Barcelona. He died leaving most of his ambitious projects uncompleted.

Fardella celebrates Descartes as the first philosopher to have provided a proper method of philosophical investigation: as in mathematics, truth must be pursued by following only clear and certain inferences. Not only the rationality of Christianity, but also Descartes' metaphysics itself could profit from a firm application of the method. For, on its basis, it is possible to argue against the existence of the material world, as Fardella argues in the second appendix to *Universae philosophiae systema*. The mind is acquainted only with its ideas which are more like conceptual dispositions than images, and can be innate (God and mathematical principles) or acquired. Ideas are not different from their references, but since they could be exactly the same even if their ontological source were only another mind - Fardella denies any distinction in this respect between primary and secondary qualities - there is no reason to postulate an unlimited domain of independent, material bodies on the basis of a limited perception of appearances. This does not mean that only minds are real. The notion of a material substance is epistemologically redundant, but God still guarantees the existence of physical bodies, a conclusion that Berkeley explicitly criticized in his *Notebooks*. It does imply, however, that we should refrain from endorsing the Cartesian equation between *res extensa* and matter, and the subsequent mechanical physics of vortex.

Fardella interprets mathematics like Galileo, as the art whereby God created the universe, and infers that the world is intrinsically mathematical and that a science of nature must be quantitative. But then, instead of material substance we should speak of geometrical points, unextended atoms somewhat similar to Leibniz's monads, acting as the source of extension. The mind itself, whose actions Fardella places in the brain, is a mathematical point, immaterial and unextended. How this ontology might be possible, Fardella never made completely clear. Leibniz and Bayle objected that such geometrical points could not be material, or they would divisible, but could not be purely mathematical either, otherwise they would not give rise to extension.

Fardella's critique of our belief in the necessary existence of an external world remains nevertheless original. It differs both from Malebranche's position (Fardella does not provide probabilistic arguments for an external world), and from that of Berkeley (Fardella does not deny the existence of a mind-independent world). Unlike Descartes, Fardella maintains that God leaves us free to withhold our assent to any impression, and that our belief in the existence of material bodies is justified only by our faith in the revelation of the Holy Scriptures. Fardella's ontology is based on a weak understanding of the principle of sufficient reason, resembling the one endorsed by Samuel Clarke in his correspondence with Leibniz, according to which God's will is a sufficient *ratio essendi* of the external world.

LUCIANO FLORIDI

List of works

The first three works were meant to be part of a larger and very ambitious system of ‘philosophia architectonica’ which Fardella never completed.

Fardella, M. (1691) *Universae philosophiae systema*, Venice.(A textbook of philosophical logic in five sections: on the origin of error, the theory of perception and judgment, the principles of reasoning and the method of investigation. The second of two appendices contains Fardella’s anti-materialist argument.)

Fardella, M. (1691) *Universae usualis mathematicae theoria*, Venice.(The first comprehensive presentation of the various branches of mathematics to be written by an Italian according to the Cartesian method.)

Fardella, M. (1698) *Animae humanae natura ab Augustino detecta in libris de Animae Quantitate, decimo de Trinitate, et de Animae Immortalitate*, Venice; partial Italian trans. R. Venza (1991-2) as ‘L’Opera Filosofica di Michelangelo Fardella’, pts 1 and 2, *La Fardelliana* 10: 107-49 and 11: 107-64.(Meant to show how Cartesian rationalism combined easily with Augustinian spiritualism. The mind or soul is represented in Leibnizian terms, as a metaphysical point. Epicurus and Lucretius are the main polemical targets of Fardella’s anti-materialism.)

Fardella, M. (1691-1709) *Lettere ad Antonio Magliabechi*, Cassino: Editrice Garigliano, 1978.(Sixty-nine letters on disparate topics written by Fardella to the famous Florentine librarian.)

Fardella, M. (1698) *Pensieri Scientifici e Lettera Antiscolastica*, Naples: Bibliopolis, 1987. (A critical edition of two previously unpublished manuscripts. The *Lettera Antiscolastica* is a powerful and detailed attack against scholasticism in all fields of knowledge, from logic to physics and metaphysics.)

Farrer, Austin Marsden (1904-68)

Austin Farrer is widely regarded as the Church of England's most brilliant philosophical theologian of the twentieth century. His elegant, sometimes difficult, writings aim more at synthesis and the elaboration of images than at analytical rigour; they characteristically take the form of a running debate between opposing positions. He focuses on the relations between divine and creaturely action in the spheres of nature, revelation and grace.

In the foreword to *The Freedom of the Will*, Austin Farrer writes:

> A host of able men, their wits sharpened by logical training, have written ingenious papers lately in the philosophical journals, each discussing voluntary freedom within the area of a carefully limited question. I could not hope to vie with their detailed thoroughness, or formal elegance. If I was to contribute anything, it would have to be by aiming at greater completeness, and at a synthesis of topics. So that is what I have done, well or ill.
>
> (1958: v)

This statement could aptly serve as a description of Farrer's entire philosophical output. He had an acute awareness of the metaphorical character of much apparently literal thinking, and an unrivalled deftness in penetrating and extending those metaphors, as his sermons and exegetical writings bear witness. And he was loath to take up any issue piecemeal. These features of Farrer's thought perhaps explain why his writing seems to lack rigour in comparison with those 'ingenious papers… in the philosophical journals'. They certainly make impossible the task of summarizing his thought in a short space. (Readers who want a quick introduction to Farrer's mature thinking on natural theology and on human freedom can do no better than to read his summaries at the end of *Faith and Speculation* and *The Freedom of the Will*.) So this entry will focus on an issue that was central to Farrer's thought: the relation between divine and human action.

The bare assertion of the existence of God, Farrer says, is 'of metaphysical interest only'. Practical importance attaches instead to assertions about God's particular actions. Since religion is precisely the voluntary association of one's own action with the divine, there can be no religion without some conception of how God acts in the world. And so a central problem for Farrer is how to conceive the relation between divine and creaturely action. Surprisingly, though, he insists that the 'causal joint' between infinite and finite action cannot be of any practical concern to us. The Christian holds that the divine action embraces whatever happens. But every event in our world is an immediate act of natural agents - otherwise it would be no part of our world. So:

> God's agency must actually be such as to work omnipotently on, in, or through creaturely agencies without either forcing them or competing with them. But as soon as we try to conceive it in action, we degrade it to the creaturely level and place it in the field of interacting causalities. The result can only be (if we take it literally) monstrosity and confusion.
>
> (1967: 62)

Given this position, the problem of human freedom and divine predestination in the achievement of salvation disappears. 'We know that the action of a man can be the action of God in him; our religious existence is an experimenting with this relation' (1967: 66). But since we cannot conceive the manner in which God acts, we cannot pose the question of the relation between his action and ours. Similarly, there is no room for a special concept of grace. 'Grace is an action of the Creator in the creature. He acts in the creature everywhere; when he acts in the rational creature he is pleased to act in that creature's mental and voluntary life, bringing them into his own' (1967: 67).

Farrer's understanding of revelation also depends on this conception of divine and human action. When we try to understand the experience of receiving a divine communication, we are often preoccupied with trying to locate the 'point of punctuation' between the divine and the human. But no such question should arise. God's will is always taking effect in the actions of his creatures. The events that make up revelation are simply those actions of God for the eternal salvation of his rational creatures 'in which the relation of human instrument to divine act becomes transparent' (1967: 103). 'God reveals himself effectively through fallible minds and takes care that their

imperfections shall not frustrate his purpose' (1967: 102).

Fascism

'Fascism' is a term referring both to a political ideology and to a concrete set of political movements and regimes. Its most prominent examples were the Italian and German regimes in the interwar period. Fascist ideology is sometimes portrayed as merely a mantle for political movements in search of power, but in reality it set forth a new vision of society, drawing on both left- and right-wing ideas. Fascists stressed the need for social cohesion and for strong leadership. They were more concerned to revitalize nations by cultural change than to propose institutional changes, but they saw themselves as offering a third way between capitalism and communism. There was no fascist philosophy as such, but fascist ideology drew inspiration from earlier philosophers, most notably Nietzsche and Sorel, and was supported by several contemporary philosophers, including Heidegger, Gentile and Schmitt.

There has always been a small number of philosophers and historians willing to concede that fascism has a serious intellectual pedigree. Some have traced its origins to Rousseau's concept of the 'general will' or Hegel's defence of the state. More commonly, the focus has been on the new nationalism which became prominent during the late nineteenth century, and which is best epitomized by the writings of Barrès or the German *völkisch* (blood nationalist) theorists such as de Lagarde. Whereas the nationalism associated with the French revolutionary doctrine of 'sovereignty of the people' tended to be universalistic and humanistic, the new strand was more emotive, stressing the bonds which linked the holistic community (see Nations and nationalism §2). This in turn was often linked to the rise of a more systematic form of racist thinking, inspired both by developments in science - especially Darwinism - and by a reading of history which saw nation and race as the main engine of change and conflict (see Race, theories of).

Other major sources of influence which have often been highlighted are the writings of Nietzsche, with his emphasis on the 'will to power', leadership and the total decadence of European bourgeois society, or Sorel's belief in the importance of myths as a means of motivating the masses (see Sorel, G.). These philosophical developments were reinforced by new ideas in the social sciences emerging at the turn of the twentieth century. Of particular importance was the work of elite theorists like Michels and Pareto, who argued that democracy was an impossibility, and the theories of psychologists like Freud and Le Bon, who pointed to the essential irrationality of much human behaviour.

These precursors were not, however, fascists in the full sense. Nietzsche, for instance, was opposed to anti-Semitism and emotive German nationalism - yet these were to be central elements in Nazism. Sorel was a revisionist socialist concerned with the problem of how to achieve a revolutionary working class, whereas the *völkisch* thinkers were nothing if not conservative. The First World War provided the impetus for fascism to develop as a more coherent ideology, synthesizing a variety of elements in pre-fascist thought.

Fascism took its name from the *fasci di combattimento*, a movement founded in 1919 by Mussolini, an ex-socialist attracted to nationalism as a means of uniting the people and promoting economic development which could fund radical social reform. Similar movements emerged elsewhere, sharing a set of ideological dispositions, although some, like the Nazis, did not normally refer to themselves as fascist.

The starting point was a view of human nature: fascists like Valois reversed Rousseau in the sense that they believed that 'man' was a savage until given a purpose by strong leaders. The need for a new fascist man was linked to a cyclical view of history, which saw conflict as inherent in the world: Hitler argued that it was necessary to ensure that the nation was sufficiently revitalized to withstand challenges from outside. Social cohesion required the destruction of deleterious humanistic or individualistic influences, like religion and liberalism, whilst the need to forge social unity made fascist theorists like Gentile and Schmitt hostile to the class analysis preached by much of the left (see Gentile, G. §3). In general, fascists paid little attention to specific institutional forms, preferring to talk vaguely about a Third Way (neither left nor right, rather lying between capitalism and communism), or the need to find a new sense of being - a major reason for Heidegger's conversion to fascism (see Heidegger, M. §1). The main focus was on changing culture and on the propaganda that was seen as necessary to do this, for fascism held that people were essentially swayed by myths and symbols rather than by rational argument - although some fascists, such as De Man and Mosley, were capable of developing serious economic and political programmes

based on a form of authoritarian and statist corporatism.

There were important differences between specific national manifestations of fascism. Nazism, for instance, saw the basis of the community as lying in ‘blood’, whereas Italian Fascism saw nationalism more in terms of culture. Thus, early fascism had no serious anti-Semitic side, or developed racial theory although it had an ethnocentric commitment to colonial expansion). Most Nazis also placed far less emphasis on the role of the state than Italian Fascists, seeing the state as a repository for reactionary elements and a source of division between the people and its leader. Moreover, some fascist intellectuals, like Drieu La Rochelle, were more concerned with the threat (from both internal decadence and more virile external enemies) to European rather than specifically national culture.

Linking all true examples of fascism, however, was a broad desire to revitalize society by forging a *holistic-national-radical-Third Way*. This characterization is flexible enough to embrace diverse examples of fascism like Nazism and Italian Fascism, while excluding other alleged cases such as General Franco’s Spain as too conservative. It is also capable of encompassing the more subtle form of post-war intellectual fascism, such as the writings of the key *nouvelle droite* theorist, de Benoist.

Sternhell, Z. (1986) *Neither Right Nor Left*, Berkeley, CA: University of California Press. (Argues both that fascism was a serious ideology and that French fascism, by not having to deal with the problems of office, produced the purest form of fascist theory; part of a trilogy, beginning in the late nineteenth century with Barrès.)

Sternhell, Z., Sznajder, M. and Asheri, M. (1994) *The Birth of Fascist Ideology*, Princeton, NJ: Princeton University Press.(Sternhell sees fascism as based on nationalism and socialism. Covers both France and Italy,

and pays particular emphasis to the impact of Sorel and anti-Marxist socialism. Sternhell does not consider Nazism to be fascist on account of its biological racist core).

Fatalism

'Fatalism' is sometimes used to mean the acceptance of determinism, along with a readiness to accept the consequence that there is no such thing as human freedom. The word is also often used in connection with a theological question: whether God's supposed foreknowledge means that the future is already fixed. But it is sometimes explained very differently, as the view that human choice and action have no influence on future events, which will be as they will be whatever we think or do. On the face of it this is barely coherent, and invites the assessment that fatalism is simply an expression of resigned acceptance.

Taken as meaning exactly what it says, the dictum that human choice and action have no influence on future events is absurd, since any action must make some aspects of some future events different from how they would have been had that action not been performed. If I leave the house, then *something* happens in the future which would not have happened had I not left it, even if that just turns out to be my rapid return to where I would have been had I stayed at home. Likewise, unless we are to deny that how we decide to behave ever has any effect on how we actually do behave, we must agree that our choices of action frequently affect future events. So if fatalism is not to fall into immediate incoherence, it must be understood rather differently, perhaps as saying only that there are *certain* things destined to happen irrespective of what we do. (Usually these will be events of particular significance: the soothsayer's prediction will come true, regardless of any attempts we may make to ensure that it does not.)

It follows that fatalism, in this form, cannot be supported by any argument which, if it worked at all, would apply to all future events. Any argument for thoroughgoing causal determinism would fall into this category. So would the notorious argument from the sea-battle: if there will be a sea-battle tomorrow, it is true now that there will be; if there will not, it is true now that there will not be. So since one of these is true now, there is nothing we can do to influence whether there will be a battle or not. If this reasoning works, it works for every future event. But in any case, although this argument and variants of it are found, it faces a severe difficulty. For it will have to address the crucial question about the direction of dependence: does the occurrence of the battle depend on the truth of today's statement, or the truth of today's statement on tomorrow's events? The fatalist conclusion calls for the former, but the latter is far more plausible and the basic argument does nothing to refute it.

Fatalism can appear more coherent if seen against a certain kind of background. Whether it appears more plausible depends on the reader's attitude to the background, which many will find rather too superstitious for their taste. We are to think of powers, watching over human life, who have decreed that certain things shall happen to certain people (that a particular individual will die young, that Oedipus will kill his own father), and are bent on manipulating the world, and perhaps also the fated individual's state of knowledge, so as to bring their decrees about. Imagine a rat in a maze, from which you have decided that it will never find its way out. If it turns left (which leads to the exit), you take out a piece from somewhere else in the maze and slot it in round the next corner, turning the chosen route into a dead end. If it turns right, you do nothing, since the right turn leads to a dead end anyway.

It should be noted that fatalism, understood in this way, has very little to do with problems about the freedom of the will. In choosing which way to turn, our rat can be free in the strongest sense that any libertarian has ever dreamed of; the fates make their move after it has made its choice. Oedipus may be equally free; the fates make sure that he does not know who the obstructive old man at the crossroads really is. Had he known that, no doubt he would have made his free choice differently, leaving the fates to outwit him in another way on another occasion.

Fatalism, Indian

*Indian speculation about the vicissitudes of human life has a long and complex history. Life in the early Vedic period was considered to be largely hostage to the 'fate' of natural and psychic forces controlled by various gods (*devas*). Fate was what proceeded 'from the gods' (*daiva*), who were considered to be the guardians of the cosmic order and the ultimate source of prosperity. Sacrifice and prayer were the principal means to win their favour.*

Later the idea arose that one's present lot is due, not to the whim of some god, but to karma, the effect of one's own actions performed in this or previous lives. On this view, humans do have some scope or 'freedom' to change themselves and the environment in which they live. This more individual potential is called puruṣakāra, *which, to varying degrees, may modify* daiva. *The literal meaning of this term is 'human action' (from the Sanskrit for 'man' and a verbal root meaning 'to act'). With the increasing popularity of the karma theory,* daiva *tended to become equated with the effects of past behaviour.*

Finally, in the context of the spiritual ascent towards a unifying vision of existence, the status of human agency itself became an issue. As long as the seeker remains blinded by false notions of 'I', the ego must experience a sense of agency and a modicum of freedom to chart its course of life. However, from the perspective of enlightenment, or mokṣa, *all is 'fate' in the hands of a personal God or a Supreme Self.*

1 Background

The concept of 'fate' (*daiva*) is already well known in the *Ṛg Veda* (completed before 800 BC), the earliest of the sacred texts of modern Hinduism. Here fate is simply the favours obtained from the gods in return for praise or sacrifice. Sacrifices are performed to ensure the good order of the world, to secure a boon or to remove impurity associated with 'sin' (for example, disease). This seeming dependence on the whims of the gods changes rather dramatically, however, at the somewhat later period of the Brāhmaṇa texts (no later than 600 BC), when the priests take control of the gods themselves through their knowledge of the sacrifice. Power is understood to reside in the ritual itself rather than in the gods (who are virtually forced to act). The belief also arises that the cosmic powers can be harnessed by means of ascetic practices known as *tapas*, and by the appropriate use of incantations or mantras. This new magical tradition received its orthodox stamp of approval in the *Atharva Veda*.

There is still little at this period to suggest the existence of a 'person' in the modern sense of an autonomous, self-directing centre of willing and doing. The human agent remains at the mercy, as it were, of external forces. Plans to shape one's own future 'destiny' (in the form of prosperity, progeny, and so on) rely less on an inner sense of agency than on the power of gods, ritual or magic to exert control over the general order of the world. Furthermore, the esoteric knowledge on which this control is based is not in the hands of the individual, but remains a closely guarded secret of the priestly caste.

A shift towards the assertion of more distinctly human powers is signalled by the emergence of a doctrine of moral causality, subsequently known as the karma doctrine. First presented in the Bṛhadāraṇyaka Upaniṣad, this doctrine came to represent the hard facts of human life not as fate, but as the inevitable result of past behaviour. The results of all deeds, good or bad as the case may be, must ultimately bear fruit in one form or another. There is no such thing as chance or luck, and even the intervention of God himself becomes problematic in certain traditions. We are punished not *for* our sins but *by* them.

The doctrine drew its logic from the companion belief in reincarnation. Eventually, life itself, including character, the circumstances of birth, the span of life, and even the daily alternation of pleasure and pain, came to be regarded as the maturation of attitudes and actions in this and previous existences. In sum, the cumulative effects of the past are seen progressively to take the place of fate as the source of human character and circumstances.

2 Fate in the *Mahābhārata*

The *Mahābhārata* (probably compiled between 200 BC and AD 300-400) is a great repository of ideas on fate in the Indian context, moving from those reminiscent of the early Vedas to concepts of divine grace and the mature doctrines of karma. A humanization of divine powers is implicit in the circumstances surrounding the central subject of this epic, a great fratricidal war whose roots are anchored in a conflict of gods and demons for control of

heaven. For example, the difference between gods and humans is blurred by the fact that the battle is being waged on the earth, where human 'sons' of the divine prototypes battle for control of a dynastic succession. More importantly, this divine infusion has evidently sired in humans a sense of an inherent power of their own.

The most common Sanskrit term for this human capacity for self-effort is *puruṣakāra* (literally 'human action'). Only what is preordained by universal consensus of the heavenly gods is now sure to prevail on the Earth. Humans are otherwise at liberty to challenge the gods, although they do so at their peril since these gods may be jealous, or even fearful, of human aspirations. Indra, the king of the gods himself, can feel threatened by the fierce austerities of some power-hungry sage. The best-laid human plans may thus be blunted or bent by a *daiva* that confronts the individual either from within, as an eruption of doubt, inner conflict or irrational behaviour, or from without, in the form of some untoward reversal of fortune. The respective spheres and strengths of these two forces is a popular topic of learned discussion in the epic.

From the macrocosmic perspective, the fate of the cosmos is in the hands of Viṣṇu-Nārāyaṇa in his supreme aspect. It is he who controls the Wheel of Time (*kālacakra*), the immense temporal cycle of creation (activity) and destruction (quiescence) of the seven worlds (*lokas*). It is he too who must provide the superordinate backing to settle the difficult or contentious rulings of Brahmā, the epic arbiter of heavenly disputes. At the human level, the fate of society is governed by a 'morality' of world ages (*yugas*) that repeat themselves with chronological precision as long as the universe is in being. The crisis that arises at each low point of moral decay can only be resolved by the eschatological destruction of the old order of society by the Divinity in his lower, human, aspect (*avatāra*). The *Mahābhārata* is essentially the (quasi-) history of one such intervention, which follows upon a prearranged heavenly accord between the old Vedic gods and Viṣṇu-Nārāyaṇa, incarnated as Kṛṣṇa. He does no actual fighting, but it is his strategic guidance that leads the human 'sons' of these gods to eventual victory.

As events escalate towards their momentously regenerative climax, the fate of individuals becomes ever more hopelessly caught up in the chain of events. Not surprisingly, the protagonists tend to rail against fate, as their own ambitions encounter inexplicable reversals in the world around them. This is particularly true of blind King Dhṛtarāṣṭra. As Kaurava losses mount, he becomes more and more convinced that he is the victim of a fate opposed to reason and human volition. *Puruṣakāra* appears increasingly ephemeral, inconsequential or futile as he is dragged from one disaster to another by his own emotional attachment to his son. These feelings are expressed in an endless litany of complaints against cosmic justice.

The more widely held belief, however, is that human planning can succeed through *puruṣakāra*, provided the undertaking is in accord with the prescribed order of *dharma* (see Duty and virtue, Indian conceptions of §§1-2). *Puruṣakāra* is considered a particularly vital quality for a king, whose *dharma* is to protect the all-important Brahmans and his subjects as a whole. The important watchword 'Victory is where the *dharma* [or Kṛṣṇa] is', is not only a harbinger of victory on the battlefield; it also has important spiritual overtones. Whatever the challenges of the world, it is believed, these can only be successfully met if individuals are able to change themselves for the better through self-control and spiritual insight. The epic expresses this notion in the well-known imagery of the chariot: one must learn to control the chariot of the body by taming the wild horses of the senses with the reins of the intellect.

This mastery of the unruly senses through the intellect (*buddhi*) underlines the epic, and subsequent Hindu, idea that volition is not a separate act in itself, but follows automatically upon an act of spiritual insight. However, while *puruṣakāra* is an important element in this process it must not be confused with 'free will' or the modern concept of freedom. What is regarded as free is not the executive function of an empirical self (*jīvātman*) but the *puruṣa* or *ātman*, the self-realized transcendental Self (see Self, Indian theories of §1). The great problem of human life is precisely the bondage caused by the ego-centred self and its 'will'. Even full control of the chariot is not true freedom, since the very need for control implies that the unruly senses are still drawn by various desires to their worldly objects. The empirical self may identify with particular motives and will them to the extent that it casts its lot in with them. But in doing so, it effectively squanders its freedom, since it is precisely the identification of the *ātman* with these various dispositions and impulses that constitutes what the *Bhagavad Gītā* regards as the false notion of 'I' (*ahaṃkāra*), with its sense of agency.

These ideas can only be fully understood in the broader context of the ascent of life through many lives and life forms (exemplified in an epic story of a lowly worm that finally becomes Brahmā). Humanity is regarded as a sort

of bridge between the animals and the gods, the point at which instinct gives way to the need for self-control, and where consciousness becomes the possibility of knowledge of the Self. On the one hand, a human birth is the envy of the lower orders of being. On the other hand, the soul now finds itself in a difficult predicament. It no longer automatically follows the *dharma* of its species (like the animals), but it is also not yet able consciously to follow the imperatives of *dharma* as if they were its own (like God himself). Instead, it faces the arduous task of battling the atavistic forces of desire, aversion and anger that constantly seek to usurp the throne of the higher values and ideals that point the way to its own transcendence. The fratricidal war itself is a fitting metaphor for this human struggle on the 'field of *dharma*' between a lower nature experienced as the 'fate' of the gods or past karma as the case may be and a higher nature acting as a proxy for the spirit (Kṛṣṇa) that takes no active part in the conflict.

The protagonists face further complications over the many branches of *dharma* itself. Conflicts of values cause confusion and heartache, making it even more difficult to know what course to take. King Yudhiṣṭhira, the son of the god Dharma no less, is notably torn between the *dharma* of Brahmanical world-renunciation (*nivṛttidharma*) and the active *dharma* (*pravṛttidharma*) of the warrior king. Arjuna too, the main hero of the epic, is moved by caste and family values to avoid his moral obligation as a warrior chieftain to 'get up and fight' this war. It takes Kṛṣṇa himself to resolve this issue by transforming the traditional Brahmanical practice of renunciation into its inner form. Any undertaking, says Kṛṣṇa, including the most inhuman violence against one's own kith and kin, can be 'right' for the world and for the individual (that is, can be *dharma*), provided it is performed with no thought of personal gain (*karmayoga*), and in a spirit of devotion to Kṛṣṇa (*bhaktiyoga*). This suggests that *puruṣakāra* is no longer judged for its outward function or form, or even for the results to which it leads, but for the spirit that animates it from within.

3 Subsequent elaborations

The later commentaries generally treat the problem of fate in the context of discussions about *mokṣa* or spiritual freedom, the final goal of this spiritual journey. This is due to the fact that, psychologically, *mokṣa* involves a quantum shift in self-identity, in which the human ego, together with its sense of agency, is transcended in favour of a larger system of identity described in the *Bhagavad Gītā* as 'the self of the self of all beings'. Since *puruṣakāra* is based on ideas of 'I' and 'mine', it is fated to dissolve with the ego into the larger 'fate' of the will of God. This interplay between the individual and God raises the issue of the identity of the real agent of action. The consensus in the principal philosophical schools is that, ultimately, it is the Supreme Divinity (*puruṣottama*) who is the agent. Śaōkara and Rāmānuja both approach the issue in the context of their respective theories. Arguing from the relative standpoint in *Brahmasūtrabhāṣya* 2.3.42, Śaōkara reverts to the traditional mode of thinking that the soul (*jīva*) is driven by a god, in this case the personalized form of the Supreme Reality (*īśvara*) acting in accord with the previous efforts of the soul itself. In *Śrībhāṣya* 1.3.41, Rāmānuja too argues that the Lord is the source of all agency. However, being more conscious of preserving the integrity of the Vedic injunctions, he manages to salvage some responsibility for the individual by falling back on his theory of qualified difference. Since the embodied soul (*jīvātman*) is independent of the Supreme Self it can act on its own. However, the latter is still given the final word in 'granting permission' for the soul to act.

Later views on fate thus develop along the lines of subsequent religious beliefs. Ascetic traditions such as Vedānta accept self-effort as a practical fiction that dissolves with the advent of true knowledge, at which point one would no doubt view all of creation as moved by fate. However, in devotional sects for whom the permission, assistance or 'grace' of a personal God is called for, the devotee in some sense remains separate from God. In this case, the soul surrenders to the higher Divine Agency and itself becomes an instrument of fate. An example of this would be Kṛṣṇa's exhortation to Arjuna to be his chosen instrument of cosmic destruction.

In the last analysis, therefore, fate is all. In terms of the tasks and responsibilities of everyday life, humans may be regarded as enjoying a modicum of freedom to chart their own course of life, thereby modifying their individual fates. However, from the perspective of the higher freedom of *mokṣa*, this self-concept is inherently flawed, the sense of 'action' and freedom being nothing but fate in disguise.

Fazang (643-712)

The monk-scholar Fazang is one of China's great Buddhist thinkers. Drawing on Buddhist scriptural literature and exegetical and systematic works of his predecessors, he fashioned a highly elaborate philosophy that served to provide a rational explanation of his vision of the way things really are. Huayan philosophy is an attempt to show rationally and systematically how the many phenomena that make up existence abide harmoniously in a double relationship of identity and interpenetration. Fazang was credited by his successors with being the third patriarch of the Huayan school.

Fazang was born in Changan (modern Xian), at that time the capital of China. He left home in his mid-teens to study Buddhism, and after several years met Zhiyan, who became the second Huayan patriarch. With Zhiyan he became acquainted with the *Huayan Sūtra* and its depiction of the cosmic identity and interpenetration of the many individual entities that constitute existence. Fazang became a monk in his mid-twenties and settled in a monastery in Changan as a scholar. He assisted Diksānanda in the latter's translation work, where he became intimately acquainted with the Mahāyāna Buddhist texts and doctrines that later would be cited in support of his portrayal of reality. Along with his translation work and his exegetical and commentarial writings, he composed several treatises that attempt to communicate the Huayan world view.

Fazang's more important works include the *Huayan wujiaozhang (Huayan Treatise on the Five Doctrines)*. Ostensibly a work on doctrinal classification, this text is the most important source of the complete Huayan system. He also composed the *Huayanjing tanxuanji (Notes on Searching for the Profundities of the Huayan Sūtra)*, an enormous phrase-by-phrase commentary on the sixty-volume version of the Huayan Sūtra. His *Huayan jinshizizhang (Huayan Essay on the Golden Lion)* is a demonstration of identity and interpenetration using the image of a golden lion as a device. The *Banluoboluomituo xinjing liushu (Brief Commentary on the Sūtra of the Heart of Prajñāpāramitā)* is a phrase-by-phrase commentary on the extremely influential Sūtra on the Heart of the Perfection of Wisdom. In the *Qixinlun yiji (Notes on the Meaning of the Treatise on the Awakening of Mahāyāna Faith)*, he provides a commentary on the enormously influential text mentioned in the title.

The Huayan philosophy is the result of Fazang's attempt to provide a reasoned, coherent description of what he believed to be the enlightened vision of the Buddha. This grasp of reality reveals a cosmos in which each individual particular is identical with all other particulars and at the same time interpenetrates with them. No thing exists in and of itself but rather is both the conditioned result of the many and a condition for all others. Consequently, the real cosmos is a place where all things of whatever nature are bound together intimately in a vast net of relationships.

This description of the true state of things is presented as the highest, final teaching of Mahāyāna Buddhism, and since Fazang's time, most Mahāyāna schools have accepted it as the high water mark of Buddhist thought. It was assembled from several parts that were central and foundational to Mahāyāna Buddhist thought and practice. One element is the doctrine of emptiness (*śūnyatā*) which, as a critique of things, is the denial that individuals exist autonomously by virtue of substances or essences. Primarily a critique of language but also secondarily a critique of the material world, 'emptiness' means that anything exists solely as the result of a vast array of conditions that generate and maintain the individual (see Buddhist concept of emptiness).

Another source of Huayan is the doctrine of the 'womb (or matrix) of Buddha' (*tathāgatagarbha*). In its simplest form, this is the doctrine that human beings are like wombs in which the seed or embryo of Buddhahood grows. In its most radical form, it teaches that everything, animate and inanimate, contains the Buddha and is thus both an ordinary, mundane individual and the body of the Buddha. Fazang also drew heavily on his predecessors in China, such as the Dilun School and the Shelun School, and on influential texts such as the *Awakening of Mahāyāna Faith* (see Buddhist philosophy, Chinese; Awakening of Faith in Mahāyāna).

Huayan thought should be seen as Fazang's attempt to unpack and develop the basic teaching of emptiness. If things are empty of independent existence, then if we examine any individual *x* in its relationship with the total environment, it will be seen that *x* arises out of a vast array of conditions and remains dependent on them. However, by the same token, because all things are simultaneously empty and existent, *x* in its capacity of being an

actual entity acts as a condition for the others. In this way, each item of existence is at once an actual fact of existence and empty. As conditions for others, all things retain their unique characteristics and qualities; as empty results of others, all things are identical. As a concrete individual with its own peculiar characteristics, the conditioning entity is simply one phenomenal item among myriads; as an instantiation of emptiness, it is the noumenous body of the Buddha Vairocana. The deluded see only the ordinary and phenomenal; the enlightened see the Buddha in each thing.

The Huayan cosmos is fundamentally and essentially a dynamic and creative place. Each individual is the focal point of vast number of causes and conditions that impinge on it and modify it from moment to moment. The ever-changing individual simultaneously acts creatively on its environment, for to be an existent being is necessarily to possess conditioning power. Such a situation has great implications for how the human individual grasps his or her own status and function in the world and for how one should act in a world where the fundamental fact is codependence.

Fechner, Gustav Theodor (1801-87)

Fechner was a pioneer in experimental psychology and the founder of psychophysics, the speciality within psychology devoted to quantitative studies of perception. In his foundational Elemente der Psychophysik (Elements of Psychophysics) (1860), he defined the mission of the new science to be the development of an 'exact theory of the functionally dependent relations of... the physical and the psychological worlds'. It is in this work that Fechner developed the law of sensation-magnitudes (Fechner's Law): the strength of a sensation is proportional to the logarithmic value of the intensity of the stimulus. Among his contemporaries he was well known not only for basic research in the field of electricity, but also as the author of a number of satirical works under the name 'Dr Mises'.

1 Life

Fechner was born in Saxony, in the village of Grossärchen, son and grandson of Protestant clergymen. Seventy years of his life were spent in Leipzig, many of them at the University, first as a medical student, then as an instructor, and finally as a professor.

Although trained in medicine, Fechner first distinguished himself in physics. While still a student he published translations of Biot's *Textbook of Physics* and Thénard's *Textbook of Theoretical and Practical Chemistry*. Under the pseudonym 'Dr Mises' he also published satirical and poetical works, the first appearing in 1821 as a *Proof That the Moon Is Made of Iodine*. It was his research on electrical currents that earned him a salaried ('Ordinarius') professorship when he was 33. But later experiments on visual after-images resulted in temporary blindness which, coupled with a harrowing nervous exhaustion, resulted in his resignation from the Leipzig faculty in 1840. A period of exile and depression followed for several years, whereupon recovered vision and restored strength permitted him to resume a productive life of research and writing.

2 Fechner's law

Elemente der Psychophysik (*Elements of Psychophysics*) (1860) is at once a defence of scientific approaches to the study of mind and a detailed treatise on the proper methods of experimental research in perception. Moreover, it contains the mathematical rationale for the derivation of what might be regarded as the first general law of perception, 'Fechner's Law', which declares the magnitude of sensations to grow as a logarithmic function of the intensity of physical stimuli.

The starting point for this derivation had been provided by the research of E.H. Weber, under whom Fechner had studied physiology and mathematics at Leipzig. Weber had shown that a constant ratio obtained between a stimulus and the amount by which it must be increased or diminished for the change to be just perceptible. Thus, a standard weight of, say, ten units might have to be increased by two units to be judged as 'just heavier'. In this case, on average, a weight of twenty units would have to be increased by four; one of thirty units by six. The general law, which Fechner named 'Weber's law', is expressed, '$\Delta S/S = C$', where *S* refers to the magnitude of the standard stimulus, ΔS to the difference or change in the magnitude of the standard stimulus sufficient to be just perceptible, and *C* to the constant fraction discovered for a given class of stimuli. It should be noted that this constant ratio obtains where the standard and the comparison stimuli are just noticeably different. Thus, for any value of the standard stimulus, the amount by which a comparison must differ to result in a just-noticeable difference (the 'jnd') is a constant fraction of the magnitude of the standard stimulus.

Weber's law is a law of discrimination, not a law relating the physical intensity of stimuli to the magnitude of the resulting sensations. To derive the latter from the former Fechner adopted a number of assumptions, chief among them that a given sensation represents (or may be taken as representing) the summation of an indefinitely large number of just-noticeable differences. He reasoned that the law of sensation-magnitude could be found by mathematical integration. Thus, by integrating the Weber ratio over all values of *S*, Fechner derived the general expression relating sensation-magnitude (*R*) to stimulus-magnitude (*S*): '$R = k \log_{\mathrm{e}} S$'. Transforming this to the base-10 system through the appropriate constant then yields '$R = k \log S$', the familiar form of Fechner's law.

Fechner developed the central ideas of his *Elements of Psychophysics* in a number of subsequent publications and extended the general perspective to the domain of aesthetics in his *Vorschule der Aesthetik (Propaedeutic to*

Aesthetics) (1876). His defence of experimental approaches to the study of mental processes and his development of methods useful for the purpose place him among the most influential figures in the history of psychology.

3 Panpsychism

Although the psychophysical research and theory were rich in mathematical and experimental content, their underlying rationale was drawn from cosmological and metaphysical conceptions somewhat misleadingly referred to asFechner's 'panpsychism'. In a number of books and articles Fechner defended the thesis that the cosmos itself has a life - an inner life not unlike human consciousness and not to be confused with its mere externals. The parallel is clear between this view and his distinction between 'inner' and 'outer' psychophysics. Inner psychophysics refers to the inner dynamics of the relations between the psychic and the physiological; outer psychophysics to the relations between stimulation and immediate experience. So too is the balance of nature impelled by animating principles not discernible in the mere outward appearances of things. A relentlessly materialistic science is doomed to ignore such principles and thus to arrive at a conception of nature that is literally meaningless (see Panpsychism).

In *Über die Seelenfrage* (*On the Soul*) (1861), Fechner criticized the conventional scientific perspective that divorced the earth from the diverse lives that arise from and return to it, rather than recognizing all living things as aspects of the earth's own inward development. A decade earlier in *Zend-Avesta* he had argued for the view that consciousness permeates all, but in a manner not accessible to prosaic modes of experience. It was only when he could once again look without pain at the flowers in his garden that he conceived of *Nanna, oder Über das seelen-leben der pflanzen* (*Nanna, The Soul Life of Plants*) (1848) in which he attributed the beauty of nature to inner principles of an irreducibly psychic sort. As he said in the conclusion of this work, 'Indeed, one will hardly believe how new and vivid is the nature which meets the man who himself comes to meet it with new eyes'.

Federalism and confederalism

Federative arrangements involve two or more governments ruling over the same territory and population. They have been of interest to political philosophers because they challenge, or at least complicate, some fundamental political concepts like authority, sovereignty, democracy and citizenship. Like citizens in actual federations, philosophers do not treat the terms of federation as a merely technocratic matter: they believe that there are morally legitimate and illegitimate ways of, among other things, dividing powers between governments, determining the representation of the subunits (for example, provinces) within federal institutions and amending the constitution. Philosophers also see in federalism a means of securing a degree of self-determination for ethnic minorities who cannot realistically expect to have their own homogeneous nation-states.

Most writers call a political arrangement federal if it has: (1) two or more levels or orders of government ruling over the same territory and citizens; (2) a division of legislative or administrative powers between these orders of government, with at least some areas of exclusive responsibility at each level; and (3) a constitutional guarantee that this division of powers cannot be changed without the agreement of governments of all orders. Contemporary federal theorists usually characterize the implications of these three conditions in a way that most philosophers prior to the twentieth century would have thought logically impossible. The combination of (1) and (2) implies that citizens of federal states are members of more than one political community and hence have a special kind of multiple citizenship; (2) and (3) imply that sovereignty in federations is divided.

An arrangement is likely to be called confederal rather than federal if effective sovereignty rests with the constituent units. In practice this is the case if the governments of the member states can unilaterally alter the terms of the arrangement, including the division of powers, or if member states can unilaterally secede from the union.

The development of federal and confederal theories in the modern era has always been closely linked to actual experiences with these sorts of political arrangements. Just before the predominance of the unitary nation-state there was widespread experimentation with leagues and confederations, including the Holy Roman Empire (800-1806), the Hanseatic League in Germany (1158-1669), the Swiss Confederation (1291-1848) and the United Provinces in Holland (1567-1798). Within these territories theorists attempted to work out a political and legal philosophy of confederation. So parallel to what was to become the mainstream tradition of political philosophy for the unitary nation-state, which begins with Bodin and Hobbes, is another philosophy which is much more receptive to federative arrangements and to what we would now call cultural and political pluralism. It starts with Althusius and Pufendorf in the seventeenth century and runs through the Abbé de Saint Pierre, Montesquieu, Rousseau, Kant, Madison and Hamilton, Tocqueville, Proudhon and Carl Schmitt, among others.

From Althusius to Kant, confederal arrangements were advocated primarily as a means of achieving international order and peace. What they contemplated in various forms was a permanent association of independent sovereign states that would delegate limited powers to a common council. Philosophical debates generally focused on three issues. The first concerned whether confederations violated the supposed indivisibility of sovereignty (see Sovereignty). Following Pufendorf, most theorists employed a distinction between sovereignty-in-itself, which remained indivisible, and the 'marks' of sovereignty - such as judicial and legislative power and powers of peace and war - which could be divided and shared within confederations. Second, there were debates about which forms of international cooperation were necessary and sufficient to realize the idea of international law. Kant's own views on this question evolved considerably in the 1780s and 1790s: as he became more optimistic about the possibility of international law for states sending delegates to a peace congress, he came to see confederations, and in particular a worldwide confederal state, as less essential for the preservation of peace. Third, there were disputes about what kinds of states could enter into the same confederation. Early writers found no objections to unions involving a mixture of feudal and republican states. But from Montesquieu and Rousseau onwards, most republicans insisted on the need for common forms of government. They saw confederation as a necessary feature of republicanism, since to be just and effective republics must be small; yet being small, they have to band together to defend themselves against larger enemies (see Republicanism). An analogous argument for the desirability of smaller political units within a larger economic union is still popular today.

The idea of federalism, as outlined above, was not seriously developed by anyone, even in theory, until the

American Confederation began to founder shortly after the thirteen colonies' seceded from Britain. Its constitution was replaced in 1789 by one setting up the first modern federation. In their brilliant defence of the new constitution, Madison, Jay and Hamilton (Hamilton *et al.* 1787-8) followed continental republicans in stressing the possibility of achieving within a federation the advantages enjoyed by both large states (security and economic strength) and small states (liberty and active democracy), without the usual disadvantages of either. Unlike Montesquieu and Rousseau, however, they paid careful attention to institutional design and argued for a strong central government responsible to a nation of equal citizens as well as to a union of states. They persuaded Tocqueville and J.S. Mill as well as the Swiss, who reconstructed their 500-year-old confederation on federal lines in 1848. Successful constitutional designs in the dozens of federations born since the late nineteenth century have all been guided by the idea of finding a division of powers and a system of federal representation that will protect diversity while encouraging a panfederal patriotism and stability (see Constitutionalism).

Concern for stability in a federation tends to introduce a number of normative considerations because in democracies political arrangements will be unstable if perceived to be unfair or illegitimate. Regional groups find an arrangement unjust if, for example, it imposes disproportionate economic burdens on them; denies them adequate representation in central institutions, such as the parliament or the supreme court; does not give them sufficient control over matters of cultural importance; or fails to recognize in an appropriate way their existence as distinct national communities. Many of these concerns involve group rights and identity politics - issues largely absent from federal debates before the twentieth century, and largely neglected by political philosophers until recently.

Feminism

Feminism is grounded on the belief that women are oppressed or disadvantaged by comparison with men, and that their oppression is in some way illegitimate or unjustified. Under the umbrella of this general characterization there are, however, many interpretations of women and their oppression, so that it is a mistake to think of feminism as a single philosophical doctrine, or as implying an agreed political programme. Just as there are diverse images of liberation, so there are a number of feminist philosophies, yoked together not so much by their particular claims or prescriptions as by their interest in a common theme.

In the earlier phases of feminism, advocates focused largely on the reform of women's social position, arguing that they should have access to education, work or civil rights. During the latter half of the twentieth century, however, feminists have become increasingly interested in the variety of social practices (including theoretical ones) through which our understandings of femininity and masculinity are created and maintained. As a result, the scope of feminist enquiry has broadened to include, for example, jurisprudence, epistemology and psychoanalysis.

Despite its diversity, this work characteristically draws on and grapples with a set of deeply-rooted historical attempts to explain the domination of women. Aristotle's claim that they are mutilated males, together with the biblical account of the sin of Eve, gave rise to an authoritative tradition in which the weakness, irrationality and ineducability of women, the inconstancy, inability to control their emotions and lack of moral virtue, were all regularly cited and assumed as grounds for controlling them and excluding them from the public realm.

1 Feminism and feminisms

While there have been, throughout the history of philosophy, writers who challenge the sexual stereotype and offer different pictures of women, their works do not contribute to a single story. It can therefore be misleading to assimilate them too quickly to the philosophical literature and political campaigns which initiated later feminist movements, or to contemporary feminist positions. Only at the end of the eighteenth century did a stream of philosophical arguments aimed at the emancipation of women begin to gather force. Only at the end of the nineteenth century did the term *la féminisme* appear, put into circulation after the fact in France during the 1890s, and rapidly taken up in the rest of Europe and then in America. The label 'feminist' thus arose out of, and was in many ways continuous with, the sequence of diverse campaigns for female emancipation fought throughout the nineteenth century - campaigns for the vote, for access to education and the professions, for the right of married women to own property and have custody of their children, for the abolition of laws about female prostitution which assumed the double standard. While the character and success of these movements varied from country to country (for example, women's suffrage was introduced in New Zealand in 1893, Finland in 1906 and Britain in 1918) they all drew upon, and generated, arguments about the nature and capacities of women and the character of their oppression, and entertained, explicitly or implicitly, images of what a better condition would be like. Many of the most influential philosophical defences of women's emancipation dating from this period were in fact written by people involved in political work - to name only two, John Stuart Mill, the author of *The Subjection of Women*, proposed to the British parliament in 1867 an amendment to the Reform Bill designed to give votes to women, while Emily Davies, author of *The Higher Education of Women*, was the foundress of Girton College, Cambridge, the first women's college of higher education in England.

We have no difficulty in retrospectively classifying works such as these as feminist, although this is not a description their authors would have used, because they contain analyses of women's oppression and proposals for overcoming it which mesh easily with analyses and proposals later regarded as central to the feminist cause. However, there are also significant divergences between feminist writers, past as well as present. Different interpretations of the disadvantages to which women are subject, allied to different conceptions of what would constitute an improvement, gave rise to distinctive and sometimes irreconcilable feminisms. Compare, for example, the broadly liberal view that the oppression of women consists in their lack of political equality with men and can be alleviated by giving women and men the same political rights, with the separatist view that women's oppression lies principally in their sexual subordination to men and can only be overcome in societies that are, as far as possible, exclusively female. As these examples indicate, there are many feminisms, each with a history of its own.

Historians are bound to select their material in the light of the kind or kinds of feminism that concern them, and to work with interpretations that are used to distinguish texts and movements that qualify as feminist from those that are merely about women. To pursue the examples already discussed, historians whose interest in feminism focuses on the quest for equality between the sexes may identify certain writers as feminists *avant la lettre*. For example, they may include in their canon Poulain de la Barre, author of *De L'Égalité des deux sexes* (1673), or Mary Wollstonecraft. By contrast, a history of feminism understood as the quest for a separate society of women is more likely to pick out Mary Astell's proposal that ladies should retire from the society of men who debar them from realizing the natural desire to advance and perfect their being, or Charlotte Perkins Gilman's utopia *Herland* about an isolated society of women who are able to have children without male assistance. As long as there is more than one interpretation of feminism, feminism will not have a unified history.

2 Renaissance and early-modern forerunners

Although female inferiority is the dominant note that sounds through the Western philosophical tradition, its character was never a matter of consensus. Long drawn out theological debates about whether woman is a human being, whether she is made in the image of God, whether she is a perfect creation of God or an imperfect version of man, and whether men and women are equal before God, all appeal to classical authorities, to the Bible and to the Church Fathers, and rumble on through the Middle Ages and into the Renaissance. Complementing them are a series of more secular discussions, of which one of the most consistent focuses on women's learning. In her *Livre de la cité des dames* (1405) Christine de Pizan extols the advantages of educating women, a theme subsequently taken up by Renaissance writers for whom it played a part in the so-called *Querelle des Femmes* - a sequence of philosophically repetitive, interwoven disputes about whether fidelity in marriage should be demanded of both sexes, whether and to what extent women should be educated, and whether women were entitled to the respect and gratitude of men for the services they rendered them. On one side of these debates, women's inferiority was reasserted by appeal to example, authority and reason. On the other, their superiority was defended in a variety of genres. Some writers - for example Cornelius Agrippa - employed the rhetorical device of the paradoxical encomium, attempting to entertain and impress by ingeniously reversing conventional evaluations of men and women (see Agrippa von Nettesheim). Others drew on a well-tried stock of cases to illustrate women's superior virtue, intelligence or judiciousness. The choice of these genres contributes to the impression that, while these champions of women sometimes propose certain social reforms, they are on the whole anxious not to unsettle the status quo. Their aim is to entertain - to tease men and flatter women, and perhaps in doing so to make both reconsider their roles - rather than to foment social change.

Traces of this style endured well into the seventeenth century and are visible even in writers who in other ways broke with the terms of the *querelle*. A particularly striking change is the move away from debates about the relative inferiority or superiority of women, to works purporting to show that the sexes are equal. Marie de Gournay, who claimed that she was the first to take this view, published her *Égalité des hommes et des femmes* in 1622, and the same theme was taken up with a new determination later in the century. In France, Poulain de la Barre adopted a fresh approach when he appealed to Cartesian scientific method: a clear and distinct understanding of the issue can be arrived at, he insists, by rational demonstration. Although his *De l'égalité des deux sexes* (1673) sometimes lapses into the older style of argument - women are more decorous and discreet than men, women's work is more valuable than that of men, and so on - Poulain is remarkable for the forthright manner with which he asserts that the relations between mind and body and the capacities of the mind are the same in both sexes, and even more for the consequences he draws from this claim. There is no reason, in his view, why women should not occupy all the public roles currently held by men. Since they are capable of equalling men in understanding all the sciences (including both civil and canon law) they could, if educated, teach in the universities, be legislators, rulers, generals of armies, judges and - most radical of all - preachers and ministers of the Church.

Poulain's willingness to contemplate such dramatic social change is unusual, but less so is his emphasis on intellectual equality and downplaying of the significance of the bodily differences between men and women. This is shared by a number of women writing in the second half of the seventeenth century, who criticize men for depriving them of learning and education, and imply that women are quite capable of ruling themselves, and indeed men. In the Netherlands, Anna Maria von Schurman writes in favour of the education of girls. In England, women such as Margaret Cavendish and Mary Astell are by turns bitter and witty in their undermining of women's subjection to men.

3 Claims of right

As early as 1673, Poulain de la Barre argued that women and men possess an equal right to knowledge, conferred on them by nature. All humans pursue happiness; no one can achieve happiness without knowledge; so everyone needs knowledge. To ensure that people are able to pursue their proper end, nature has supplied the necessary means in the form of a right. We find here the beginnings of an appeal to rights which became progressively more central until, a century or so later, it dominated debate. In the immediate wake of the French Revolution, Olymphe de Gouges presented the French Assembly with a Declaration of the Rights of Women (which it declined to ratify). Women, she argued, should have rights to employment, legal rights within the family, a right to free speech and a separate assembly in which they could represent themselves. The same theme was taken up in England by Mary Wollstonecraft, who in 1792 published *A Vindication of the Rights of Women*. Challenging Rousseau, Wollstonecraft argued that the education and emancipation of women are conditions of a truly civilized society. God has endowed all humans with reason so that they can use it to govern their passions and attain knowledge and virtue. To deprive women of the opportunity to perfect their nature and increase their capacity for happiness is to treat them as less than human and render them ‘gentle, domestic brutes’. It is to trample on their rights and keep them in a state of subjection which damages both them and their male captors.

Far from being natural, Wollstonecraft explains echoing the arguments of Mary Astell, the presumed inferiority of women stems primarily from their lack of education. Cut off from learning and encouraged to care only for love and fashion, they are unable to cultivate any solid virtues, and do indeed display the flightiness and stupidity for which they are criticized. However, as well as damaging themselves, women in this condition diminish others. First, they damage men. To treat a fellow human despotically shows a lack of virtue, and just as kings are corrupted by their excessive power, so men are corrupted by the tyranny they exercise over their sisters, daughters and wives. Second, ignorant and powerless women are unfitted to instil virtue into their children. ‘To be a good mother **-** a woman must have sense and that independence of mind which few women possess who are taught to depend entirely on their husbands’ (Wollstonecraft [1792] 1995: 243).

Although Wollstonecraft’s argument hinges on her claim that women are as rational as men, she has no sympathy for what she calls ‘masculine women’. The aim of educating women is, in her view, to make them into virtuous wives and mothers who, by fulfilling these natural duties, will become useful members of society. Freed from male subjection, educated women would not usurp the roles of men but would freely and virtuously pursue their domestic lives to the benefit of society as a whole. The claim that men and women are intellectual equals is here allied to the view that there are natural differences between them which fit them for distinct ways of life: rational women will see that their place is in the home.

This easy division of labour was put under increasing pressure during the nineteenth century, as feminist thinking became less concerned with women’s overarching moral right to liberty and focused instead on particular legal entitlements such as the right to own property, to enter the professions, and above all to vote. Nevertheless, arguments which appeal simultaneously to the equality and difference of the sexes, and sustain the view that women excel in certain domestic virtues, remained common. The US suffragist, Elizabeth Cady Stanton, demanded the vote for women from the New York legislature during the 1850s on the grounds that ‘the rights of every human being are the same and identical’. But she also argued that, if women were able to represent themselves by voting, they would make a distinctive contribution which would balance that of men.

The wish to reconcile the demands of equality and difference is also evident in John Stuart Mill’s *The Subjection of Women* (1869). Mill argues that women are entitled to the same rights as men and should be able to hold public office, to work, to own property and to vote. He also argues that married women should not be required to obey their husbands and should have custody over their children. His primary ground for these conclusions is that women and men are equal, but he supplements this argument with further claims about the benefits that the freedom of women would bring. Like Wollstonecraft, he claims that the power of men over women ‘perverts the whole manner of existence of the man, both as an individual and a social being’, and reiterates her view that there can be no true affection between spouses who have nothing in common. It is only once women are educated that there can be the solid, enduring friendship between the sexes that heralds the moral regeneration of mankind. However, two further lines of thought appeal to assumed differences. Mill first argues that women possess a distinctive aversion to war and addiction to philanthropy, of which they would make better use if they were better

informed. In addition, although women should have the right to work, Mill takes it that when they marry they make ‘a choice of the management of a household, and the bringing up of a family’ as the first call on their exertions. Older women who have completed this task may decide to direct their energies to public life, for instance by standing for parliament. But the first place of married women is, once again, in the home.

4 Sexual oppression and emancipation

The view that the oppression of women could be overcome once they had the same rights as men was therefore compatible with a conventional understanding of the division of male and female labour. But doubt was cast on this whole approach to emancipation by the fact that, once the vote was won, women did not on the whole use their new-found political power to press for further reform. Many suffragists were keenly disappointed, and feminists of more radical political persuasions were strengthened in their conviction that the source of women’s oppression did not lie in their lack of political rights. Reforms such as the married women’s property act and the right to higher education, they pointed out, benefited middle-class more than working women. More important still, the root of women’s subordination lay not in their civic but in their private lives - in their roles as wives and mothers.

This latter view was partly derived from Engels’ *Origins of the Family, Private Property and the State* (1884) in which he argued that women’s oppression is primarily sexual. There is nothing natural about the patriarchal family. Rather, this institution came into existence at a particular point in history together with private property. To be able to hand down their property to their sons, men needed complete sexual possession of the mothers of their children, and to this end they reduced women to servitude. In capitalist society, women’s subjection consists not in their lack of legal rights, but in their weak position in the labour market which in turn forces them into marriage. Women face a choice between lives of near-destitution as workers or lives of slavery as wives and mothers, or in the case of working class women, both exploitation at work and subjection in marriage. Only once capitalism is overthrown will they escape this plight and be freed from dependence.

In Russia, the predicament diagnosed by Engels was confronted by the revolutionary Alexandra Kollontai (1872-1952), who insisted in *The Social Basis of the Woman Question* (1909) that proletarian women must refuse to cooperate with the bourgeois feminist movement and attack capitalism, the source of their oppression. As Commissar of Social Welfare in the Russian Revolutionary Government of 1917, Kollontai oversaw the drafting of far-reaching legal reforms designed to revolutionize the family and sexual relations between men and women, and to relieve women of the ‘triple load’ of wage worker, housekeeper and mother. These reforms were organized around a distinction between productive and non-productive labour, and were based on the view that women should be relieved of the burden of non-productive domestic labour (cleaning, cooking, washing, caring for clothes, and many aspects of child-rearing) to engage in productive labour alongside men. In this way they would achieve economic independence. At the same time, women’s work was to take account of their productive childbearing role. The work of carrying and bringing up children was no longer to be seen as the responsibility of individual families but as a task for the state, since it was in the interest of the workers’ collective that children should be born and that they should grow up to be able-bodied and good revolutionaries.

In the early years of the Bolshevik government, Kollontai began to implement a series of radical though short-lived reforms. Women were to have full civil rights; civil marriage and divorce laws were introduced; legitimate and illegitimate children were to have the same legal rights; and in 1920 abortion was legalized. As far as labour was concerned, women’s work was to take account of childbearing. They were not to do heavy work which might damage their health or work long hours or night shifts. They were to have paid maternity leave and health care during pregnancy. As for their children, once out of infancy they were to be cared for in crèches, kindergartens and schools which would also provide meals and clothing.

According to Kollontai, the dictatorship of the proletariat will abolish the family and with it bourgeois sexual morality. For though the state must, in her view, concern itself with children, it did not have any more extended interest in the relations between their parents. Conventional notions of romantic love must not undermine comradeship; yet Kollontai stresses that solidarity can only exist between those who are capable of love and sympathy, and envisages a society in which people are emotionally educated to feel many forms of love for different people.

In the USA, Engels’ view that women’s oppression is rooted in the family was used by the anarchist, Emma

Goldman (1869-1940), to ground a different set of conclusions. Access to education and work, for which emancipationists had fought so hard, produced women who were ‘professional automatons’ and lacked ‘the essence that enriches the soul’. By entering the public sphere, women had joined an impure State which prevents both women and men from developing the inner qualities that spring from sexual intimacy and constitute freedom, but is particularly distorting for women, for whom love is even more important than it is for men. The question of how to become free is therefore a question about how to foster sexual self-expression, and Goldman is adamant that this can only happen once women cease to be the sexual possessions of their husbands. As well as eschewing the public sphere, women must reject the private institution of marriage in which, driven by economic need, they purchase financial security at the price of their independence. They must learn instead to recognize and follow what Goldman calls their instinct.

Goldman and Kollontai share with some of their liberal forebears and contemporaries the premise that an institution of marriage in which women are sexually dominated by, and economically dependent on, their husbands, makes them unfree. More radically, both claim that these evils can only be overcome by sweeping away conventional notions of marriage and family. Beyond this, however, they diverge sharply. For Kollontai, liberty consists in productive labour in which both women and men must engage if they are to be equal and equally free. In the case of women, however, productive labour can take the distinctive form of bearing children. Motherhood (women’s difference), is subordinated to an overall conception of equality according to which men and women are not treated in the same way, but make the same kind of contribution by working productively. Goldman, by contrast, conceives freedom as a state of individual exploration and self-expression which needs to be pursued outside the impurity and corruption of the State and has little to do with work. Both men and women need love in order to become free, but for women, sexual intimacy plays a particularly important part in this process. While Kollontai separates reproductive sex from other erotic relations, Goldman tips the balance away from motherhood. Unconstrained love, which may or may not be the love of mothers for their children, is what enables women to fulfil themselves and become free.

5 The pervasiveness of male domination

It has become customary to distinguish a first wave of feminism, dating from the mid nineteenth century to the 1930s, from a second wave, breaking in the 1970s. This chronology is designed to highlight the absence of specifically feminist political campaigns in the intervening period, but is misleading if applied more generally, since one of the most influential works of modern feminist philosophy, Simone de Beauvoir’s *The Second Sex*, was published in 1949 (see Beauvoir, S. de). Dissatisfied with existing accounts of women’s subordination to men, Beauvoir confronted the question ‘What is Woman?’ by exploring the limited answers offered by historical materialism and psychoanalysis. Both these theories, she claims, beg the question. In *The Origin of the Family*, Engels asserts that the institution of private property results in the enslavement of women, but offers no means of explaining why this should have been so. Equally, Freud’s account of sexual differentiation fails to say what previous evaluation of virility makes boys proud of their penises and makes girls attribute special significance to their lack of this bodily part. To explain women’s oppression, in which women themselves are complicitous, it is not enough to appeal merely to economic categories or patterns of psychological development already imbued with the evaluations that constitute male power. What is needed is a theory grounded on dynamics of consciousness running deeper than physiological, psychological or economic forces, capable of doing justice to the vast variety of practices that contribute to women’s subordination.

Beauvoir derives her analysis of woman from the existentialist view of consciousness articulated by Sartre in *Being and Nothingness* (see Sartre, J.-P.). Each consciousness faces the world alone, and must create itself through its own choices by responding to the things around it, whether these are passive natural objects or other consciousnesses. Adapting Hegel’s account of the relations between master and slave, Sartre portrays the meeting of one consciousness with another as profoundly disturbing (see Hegel, G.F.W. §5). In the gaze of the Other, a consciousness recognizes a point of view which is different from its own and unattainable, a mark of its own incompleteness. At the same time, the gaze of the Other threatens to destroy it by turning it into an object. In response, the consciousness can choose to retaliate - to objectify the Other. But in doing so it destroys an external view of itself and must resign itself to the incompleteness of its self-understanding. The consciousness is therefore caught: it can dominate the Other, or live with the threat it poses.

It is through woman, Beauvoir argues, that male consciousness alleviates this conflict. Like men, women are conscious beings capable of returning the male gaze, and yet they allow themselves to be dominated. By possessing them, men are able to control the Other without destroying it, to withstand a gaze which is not unbearably threatening. Why do women occupy this position? Why do they not try to dominate men? Although Beauvoir suggests that the comparative passivity of women originates in childbearing, she is more interested in analysing the multitude of social practices which conspire to keep women in the position of the Other and prevent them from seeking their own transcendence. These practices, she argues, are sustained both by men, who encourage and reward female passivity, and by women, who cooperate in their own domination. The latter, however, is an example of bad faith. To allow oneself to be treated as an object is to fail to realize one's being by making ones own choices, and to shirk the painful project of becoming free. How, then, are women to liberate themselves? To avoid becoming Other, Beauvoir suggests, women must abandon the roles of wives and mothers in which they are most easily objectified and compete with men through work. Once they begin to exercise the assertiveness and courage essential to freedom, conceptions of what it is to be a woman will alter, and women and men will find ways to treat one another as equals.

One of Beauvoir's most profound contributions to feminist philosophy lay in her insistence that women are dominated in all aspects of their lives. Their comparative lack of freedom does not consist merely in lack of civic rights, or in particular institutions of motherhood and marriage, although these are contributory factors. Rather, they are kept in their inferior place by 'the whole of civilization' - by a multitude of evaluations and social practices (tellingly described in chapters on childhood, the young girl, sexual initiation and so on) which shape our understandings of male and female, masculine and feminine. As she indicates in her celebrated remark, 'One is not born, but rather becomes, a women', Beauvoir holds that it is through social practices that bodies come to be understood as sexually differentiated, and through these same practices that the differences between them are invested with evaluative significance. Becoming a woman is a cultural and historical process which is never completed. Although Beauvoir allows that there will always be differences between women and men deriving from their bodily distinctions and the effect these have on their sensuality, there is no one thing that women intrinsically or naturally are. Correspondingly, there is no discernible limit to what they may become.

6 Second- and third-wave feminism

Many of the critical and constructive themes discussed by Beauvoir were taken up again in the late 1960s and 1970s (though often without much reference to *The Second Sex*) by a generation of women who struggled, in the light of their personal experience, to revise the social and psychological theories around which academic debate revolved. On a critical plane, they enlarged Beauvoir's objections to Marxism and psychoanalysis and added criticisms of other sociological approaches such as functionalism, sometimes engendering debates which remained lively throughout the next twenty or so years. For feminists concerned with Marxism, the key issues were whether women could be satisfactorily accommodated within the class structure of society, and whether women's oppression could be adequately explained in terms of their place in the relations of production and the ideologies to which these gave rise. Studies of domestic labour and of women's sexual subordination suggested that, while Marxist analyses of women in capitalist societies remained valuable, the answer to these questions was negative. Turning their attention to psychoanalysis, a number of writers launched an influential attack on what they saw as Freud's construction of femininity as a passive, masochistic, narcissistic and intellectually limited condition. These readings of Freud and his successors gave feminists pause, and initiated a series of fruitful reinterpretations and modifications within psychoanalytic theory (see Feminism and psychoanalysis; Irigaray, L.; Kristeva, J.).

This critical work was also the vehicle for a number of important innovations in feminist thinking which raised fresh questions and consolidated novel approaches. Writers such as Kate Millett and Shulamith Firestone argued in the early 1970s that the forms of domination isolated by feminists are all relatively superficial in comparison with patriarchy - the sexual power that men exercise over women, primarily within the family, but also in social, economic and political institutions. In a wide range of societies, it was pointed out, men's sexuality is the source and justification of their power, the purportedly natural characteristic that gives them the right to rule women. The workings of patriarchy are evident not just in erotic relations between the sexes, but in the manifold means by which men and women are socialized as to temperament, role and status, men being taught to regard themselves as potent and active, women to perceive themselves as subordinate and sexually impure.

Patriarchy, then, relies not so much on the biological differences between men and women as on deep-seated cultural interpretations that give them value and significance. In the early 1970s this distinction came to be regarded as crucial, and writers such as Millett and Ann Oakley took over the terms ‘sex’ and ‘gender’ to mark it: sex refers to the biological traits that make a person male or female, gender to culturally variable conceptions of masculinity and femininity. Taken together, the notions of patriarchy, sex and gender provided an Anglo-American articulation of many of the themes announced by Beauvoir, and gave rise to a series of theoretical debates, some of which are still going on. Is sex really separable from gender, or is our experience and theorizing so mediated by culture that the idea of the simply biological ceases to make sense? Is patriarchy a useful analytical category, or is it either unduly general, or unduly reductionist? How, in any case, is patriarchal power related to other forms of political and economic power? And is it really as strong and pervasive as its exponents claim?

Regardless of the fate of these questions, the belief that men’s domination of women may be sustained by all sorts of practices had a vast impact on the Academy, as feminists began to take a fresh look at the texts and theories they studied professionally. This approach proved fruitful when applied to literary texts - Simone de Beauvoir had included a study of ‘The Myth of Woman in Five Authors’ in *The Second Sex*, and Millett’s *Sexual Politics* opens with striking readings of Henry Miller, Norman Mailer and Jean Genet (see Feminist literary criticism). It was soon adopted by philosophers, who started to analyse the conceptions of gender embedded in the great works of the philosophical tradition. Genevieve Lloyd’s *The Man of Reason* (1984) and Carole Pateman’s articles on contractarian political theory are notable early examples of this kind of work, and were rapidly followed by critical scrutinies both of the various areas of philosophy and particular positions within them (see Feminist aesthetics; Feminist epistemology; Feminist ethics; Feminist jurisprudence; Feminist political philosophy; Feminism and social science; Feminist theology).

While the results of this academic flowering have been extremely diverse, two themes stand out. First, some of the most impressive contributions to this recent work have shown how philosophical standards and doctrines that have claimed for themselves an objective and universal status reflect particular interests, values and priorities attuned to broader conceptions of masculinity. In this way, philosophy contributes to the cultural constructions of gender that play a part in legitimating and maintaining men’s power over women. Second, the third-wave feminism of the 1980s and 1990s has turned its critical techniques back on feminism’s own long-standing habit of making claims on behalf of ‘women’. These purportedly universal pronouncements, it is now pointed out, fail to take account of the differences between women of diverse races, sexual orientations, nationalities or classes. Moreover, if gender is not a natural category, there is nothing to be said about women as such, and we must become more sensitive to the many conceptions of femininity found in different societies. This anti-essentialism has profound implications for feminism, both as an academic preoccupation and as a political movement, and marks an important shift away from its own origins towards new themes and questions.

Feminism and social science

Feminists have two sorts of interest in the social sciences. With the advent of the second-wave women's movement, they developed wide-ranging critiques of gender bias in the conceptual framework and methodology, as well as in the goals, institutions and practice of virtually all the social sciences; they argue that the social sciences both reflect and contribute to the sexism of the larger societies in which they are embedded. Alongside these critiques feminist practitioners have established constructive programmes of research that are intended to rectify the inadequacies of existing traditions of research and to address questions of concern to women. In this they are committed both to improving the disciplines in which they participate and to establishing a sound empirical and theoretical basis for feminist activism. This engagement of feminists with social science, as commentators and practitioners, raises a number of philosophical issues that have been addressed by feminist social scientists and philosophers. These include questions about ideals of objectivity and the role of contextual values in social scientific inquiry, the goals of feminist research, the forms of practice appropriate to these goals, and the responsibilities of feminist researchers to the subjects of inquiry and to those who may otherwise be affected by its conduct or results.

1 Feminist critiques of the social sciences

Feminist critics of the social sciences make the case, usually with respect to specific examples, that often even the most rigorous and conscientious research in the social sciences has been androcentric or sexist or both: it embodies a male-centred view of its subject matter, and sometimes explicit assumptions of male superiority. These critiques began to appear regularly in most fields in the early 1970s and quickly gained wide currency. They frequently coincided with the founding of committees on the status of women which undertook to document and to counteract inequities in the recruitment, training, employment and professional recognition of women within the social sciences. Although there are important differences in the form that feminist critiques take and in the impact they have had in various fields and subfields of the social sciences, they follow similar lines of development and converge on four broad areas of concern (Wylie *et al.* 1989).

Often the first issues raised by feminist critics have to do with the goals of the social sciences. They object that the questions central to much mainstream research reflect androcentric interests in the social world; women's activities, roles and contributions have been largely ignored, as have issues of particular concern to women (for example, violence against women, the history of domestic technologies, gender segregation in the workplace). At the very least this line of criticism suggests that the scope of social scientific inquiry should be expanded. In addition, however, feminists ask how adequate our understanding can be, even of the subjects that are typically considered, if substantial dimensions of social life have been left out of account.

A second family of objections, content critiques, draws attention to ways in which social research is compromised when its subjects are conceptualized in terms that reflect sexist or androcentric presuppositions. These include implicit, 'taken-for-granted' assumptions about gender categories and relations - about the typical (or 'natural') roles and capabilities of women and men. Male experience, behaviour, interests and attributes may be treated as normative, with the result that gender differences are ignored. In some cases the whole subject domain is characterized in male-specific terms or, when women are considered, it is exclusively in relation to men (Eichler describes these as errors of overgeneralization and gender insensitivity). Some widely cited cases include ethnographic studies in which 'hunter-gatherer societies' are characterized in terms of the hunting activities of men (Rosaldo and Lamphere 1974), and the 'man the hunter' theories of evolution informed by these accounts (Dahlberg 1981; Hager 1997), historical periodization schemes which reflect a preoccupation with the fortunes of (elite) men (Kelly-Gadol 1976), and theories of human psychological development based exclusively on male samples (Gilligan 1982; see Moral development). Gender stereotypes may also be reflected in the converse assumption that men and women are categorically different. In this case, similar and overlapping traits are either ignored or are characterized in different terms when associated with men rather than women (in Eichler's terms these are errors that arise from imposing a 'double standard' and from 'sexual dichotomism', 1988); sex difference research abounds with examples of this practice (Fausto-Sterling 1985). The central point feminist critics make is that the background assumptions underlying such 'distortions' of content should be made explicit and subjected to critical empirical scrutiny.

These critiques both generate and depend upon ’remedial’ research; the study of ‘women worthies’, ’women’s contributions’ and ’women victims’ (Harding 1986) has been crucial in establishing, in concrete terms, what androcentric social science has left out of its account. But wherever such compensatory strategies have been adopted, autocritiques have appeared which made it clear that they are not sufficient on their own. To take one example among many that could be cited, through the 1970s and early 1980s feminist anthropologists, historians and political scientists argued (often independently) that a central limitation of their respective fields of study is a preoccupation with a male-identified ’public’ domain (for example, public figures, public exercises of power, politics in a juridical sense); they urged that feminists turn their attention to the neglected, private, domestic spheres in which women are to be found. Critical reflection shows, however, that simply inverting the emphasis of previous research leaves intact precisely the gender categories and stereotypes that feminists had insisted should be called into question (Rosaldo 1980; Tomm and Hamilton 1988). To rectify the androcentrism operating at this deeper level it is necessary, not just to add considerations of (for example) the work women do, the symbolic universes they construct and the forms of power they exercise in domestic and other contexts, but to more fundamentally reconceptualize what counts as work or as power, and as the ’domestic’ or private sphere both in its own terms and in relation to ’public’ life.

By the mid-1980s it was widely noted that the effects of androcentric goals and presuppositions were pervasive in two senses. Deepening critiques of content suggested that all aspects of research may be affected, not just the formation of questions or the interpretation of results, but also domain-defining assumptions that determine the design of research, the selection of methodologies and the formulation of categories of description and analysis. Moreover, androcentric bias of one kind or another had been identified in virtually all the fields of social research in which feminists had undertaken critical analyses. A third type of critique, of research methodologies, arises when feminists ask how it is possible that androcentric bias in the goals and content of inquiry could be as deeply rooted and persistent as their collective analyses suggest.

The point of departure for methodological critiques is a suspicion that the forms of inquiry typical in the social sciences may be responsible, in some part, for the production and persistence of androcentric bias. Some feminists maintain that established methods for evaluating knowledge claims are adequate as they stand, but that they have simply not been applied as widely or as systematically as they should have been; this constitutes a form of feminist empiricism (Harding 1986). Others insist that we should reassess our faith in the capacity of these methods to expose systematic bias. They may be powerful tools for assessing the empirical adequacy, reliability and scope of specific knowledge claims within a frame of reference, but will often simply reproduce error if it is rooted in the fundamental presuppositions of inquiry. Still others suggest that some methods may actually generate androcentric and sexist bias. For example, in many contexts a central theme in feminist critiques has been a rejection of the ’naturalist’ conviction that social research must conform to models of natural scientific practice (Mies 1983; Nielsen 1990; Stanley and Wise 1983) (see Naturalism in social science). Especially when formulated in terms of positivist theories of science, this enforces a preoccupation with quasi-experimental and quantitative methodologies which may systematically obscure devalued subordinate perspectives (for example, of women) that do not conform to the conventions of dominant ideology. Although few endorse this thesis in its strongest form - few maintain that research methods are intrinsically sexist or androcentric - it is clear that, in order to recover dimensions of social life ignored by mainstream research, feminist practitioners frequently and increasingly turn to forms of evidence considered ephemeral (for example, diaries, private papers, material culture, as opposed to archives of public record) and rely on methodologies that are nonstandard or marginal by the conventions of their fields (for example, open-ended qualitative methodologies in fields dominated by naturalism).

A fourth and final type of feminist critique is also inspired by reflection on the ways in which research is typically conducted in the social sciences, especially when informed by objectivist and positivist ideals (Fonow and Cook 1991; Nebraska Collective 1983; see the summary discussions in Reinharz 1992). A recurrent theme is concern that human subjects, especially those who are disempowered by established social hierarchies, may be demeaned and exploited by research practices which require that they be ‘objectified’ or treated like objects (Stanley and Wise 1983) (see Objectivity). In this feminists join many other social scientists who have insisted on the need to take responsibility for the effect of their research practice on subjects, and to scrutinize the ways in which they, and their research enterprises, function as agents of social manipulation and control (Smith 1987).

2 Constructive initiatives

These critiques by no means exhaust feminist interests in the social sciences. As insiders to the social sciences (Westcott 1979; Collins in Fonow and Cook 1991), feminist practitioners actively work against the sexism and androcentrism they identify in extant traditions of research; in this they are concerned to improve the research enterprises in which they are engaged. In addition, as feminists, many have a strong commitment to change conditions of life that are oppressive for women and they recognize that, if they are to be effective in realizing these goals, it is necessary to understand with accuracy, subtlety and explanatory precision the nature and sources of the inequities that disadvantage women. Whatever their limitations, social-scientific modes of inquiry are among the most powerful tools available for doing this. Feminists also have an interest, then, in developing programmes of research which address questions relevant to women and promise a secure empirical and conceptual foundation for feminist activism.

In taking up these constructive projects, feminists immediately confront the questions of how research should be conducted if it is to avoid the pitfalls of androcentric practice, and whether there is any distinctively 'feminist' mode of inquiry. Consensus emerged by the late 1980s that the quest for a 'feminist method' or 'feminist science' is misguided; it bespeaks a faith in methodological solutions that feminists have long cautioned against, and presupposes an implausible unity of feminist interests. It is more fruitful to ask what it means to 'do [social] science as a feminist' (Harding 1987; Longino 1987, 1994). In this spirit feminist practitioners have typically formulated quite general guidelines for ensuring that research practice is nonsexist, and is otherwise consistent with feminist ideals (Eichler 1988; Mies 1983; Reinharz 1992). These may be characterized in terms of responses to the four types of criticism described above.

First, feminists have insisted that, at the very least, the goals of social scientific inquiry should include consideration of women and gender. In addition, many feminist social scientists advocate research that has (potential) practical import: research that addresses questions of concern to women, and that promises an understanding relevant for improving their lives.

Second, a persistent, if controversial, theme is the recommendation that feminist research should be 'grounded in' women's experience (Mies 1983; Stanley and Wise 1983). This principle is interpreted in widely divergent ways. In some cases it is understood to mean that feminist research should take women's lives and experience as a primary subject of inquiry; it should redress the silencing and devaluation of women's perspectives that is reproduced by male-normative thinking in the social sciences. Many consider this too restrictive a mandate for feminist researchers, and urge that the experience and understanding of women should serve as a basis for identifying new questions, formulating new categories of description and analysis, and expanding our interpretive repertoire; it represents a standpoint from which the limitations of androcentric thinking may be discernible in all areas, not just those in which women predominate (see Harding 1991 on 'thinking from women's lives').

Third, feminist practitioners frequently insist on thoroughgoing 'reflexivity': they hold that the theoretical and methodological presuppositions of their research should be subject to the same sort of critical scrutiny as they apply to mainstream research (Longino's 'provisionalism', 1994).

Finally, by extension of these three principles, feminist social scientists are actively concerned with issues of accountability to research subjects and to others who may be affected by the practice or results of their research. They insist that, as a minimum requirement, research practices should not, themselves, exploit or oppress women. Often they urge that research be designed, as far as possible, as interventions that may benefit research subjects and they recommend collaborative models of inquiry.

Consistent with the requirement for reflexivity, there is active ongoing debate about all these recommendations and their implications for practice.

3 Philosophical implications

These constructive guidelines for doing research as feminists, and the critiques from which they arise, pose a number of philosophical problems, foundational and epistemic. In the process of interrogating entrenched assumptions about women and gender, feminist social scientists have contributed to wider debates that substantially destabilize the assumption that these constitute coherent categories which can be presupposed as the

basis either for feminist activism or feminist scholarship. As critics of the inherent elitism, racism, and ethnocentrism of second-wave feminism point out, women's experience is so diverse and gender categories and roles so deeply structured by other systems of social differentiation, it is untenable to treat 'gender' as an autonomous category for analysis or to presume a unitary 'women's' standpoint (Anderson and Collins 1995; Mohanty, Russo and Torres 1991). This reinforces the commitment to reflexivity; it is a thoroughly contingent, empirical question how gender should be conceptualized and whether it is a relevant category for critical or constructive analysis. The interests of feminists in the social sciences thus converge on those of critics working from innumerable other subordinate standpoints.

In addition to these foundational issues, feminist critiques of and contributions to the social sciences raise fundamental epistemic questions about entrenched ideals of objectivity and the relationship of 'external' contextual values and interests to the 'internal' epistemic values generally assumed to be constitutive of scientific inquiry (Longino 1990). The extent and depth of androcentric bias identified by feminist critics makes it increasingly implausible that the difficulty lies only with instances of 'bad science'; it suggests that good science, 'science as usual', even our best science, is more deeply infused with the values and interests of its practitioners than has generally been acknowledged (Harding 1986). Moreover, where feminists working from an explicitly interested standpoint have made important contributions to the social sciences, even judged by quite traditional standards, it seems that contextual values should not always be regarded as a contaminant of inquiry (Alcoff 1987). Standpoint theorists argue, on the basis of such observations, that 'contextual' values play an irreducible role in all research practice, and postmodern critics are frequently identified as drawing strong relativist conclusions on this basis (see Harding 1986 for a summary of these positions). In practice, however, few feminist practitioners are prepared to embrace such conclusions (di Leonardo 1991; Hawkesworth 1989). This is not just a strategic stance motivated by concern that feminists' insights should be taken seriously as offering an improved rather than just an alternative understanding of the social world. It reflects, as well, an appreciation, often born of activist engagement, that it is possible to be (disastrously) wrong even about subjects as enigmatic as the cultural, intentional systems studied by social scientists. As is often observed, only the most powerful could imagine that the world is as they construct it; for feminists much depends on establishing an empirically and explanatorily accurate understanding of the world in which they hope to intervene.

The epistemological challenge posed by feminist research is to develop an account of epistemic values and ideals, such as empirical adequacy, explanatory power, objectivity, which makes sense of the nuanced judgments social scientists (including feminists) routinely make about the relative credibility of knowledge claims without requiring untenable conditions of value-neutrality or empirical foundationalism (see Foundationalism). In taking up these questions, feminists engage issues which are central to postpositivist philosophy of science (Alcoff and Potter 1993; Lloyd 1995).

Feminist aesthetics

Feminist perspectives in aesthetics and philosophy of art have emerged not only from the discipline of philosophy but also from cognate fields such as literary theory, film studies and art history. Like other feminist philosophy, feminist aesthetics is founded upon critiques of fundamental assumptions that have traditionally governed this area of study. Such staple concepts as aesthetic value, disinterested attention, aesthetic perception and fine art have been analysed for biased perspectives that explicitly or covertly favour masculine gender.

Gender bias has been located, for example, in theories of aesthetic attention and appreciation. Feminist analyses have speculated that the traditional, ideal, 'disinterested' aesthetic perceiver covertly stands in a position of masculine privilege encouraging desire and control of the object of contemplation. Calling attention to the masculine position of the perceiver goes hand in hand with analyses of visual arts and literature that focus on their representations of gender - formalist interpretive methods that ignore the portrayal of women and sexuality have been especially criticized. The paucity of female artists on lists of acknowledged geniuses and the relative absence of their work from canons of art has occasioned speculation that the concept of art itself is biased in so far as it excludes the creations of most women.

Feminist analyses stress the social contexts within which theories develop. Not only do concepts basic to aesthetics manifest ideas about gender that derive from formative traditions, but notions of beauty and art are themselves influential components of culture and contribute to the shape and perpetuation of gender roles.

1 Historical critiques

Feminist challenges to academic disciplines begin with critiques of the basic assumptions of a field and often consist of examinations of canonical texts for any gender-related implications. In philosophy, this involves demonstrating that theories that purport to be universalist, that is, to pertain generically to all human beings, are in fact models of ideal masculine nature. The gender biases of Western philosophy are often related in some way to the fundamental reliance of philosophical views on the centrality of reason. Reason is the standard faculty of knowledge and of moral responsibility, and it operates in most theories as the chief essential characteristic of being human. Reason raises the human creature above nature, making possible creation beyond what nature has given. But rationality is also a trait that is employed to contrast male with female dispositions, for the nonrational domains of emotion, sense and the body are widely associated with femininity. Thus many theories that at first glance seem to be general views about all people may be discovered to refer standardly to men, and sometimes actually to exclude women. In the history of aesthetics, reason is often not the chief faculty governing artistic creativity or aesthetic experience. However, still operative in aesthetic theory are the binary correlations that link reason to masculinity and the transcendence of nature, and that associate emotion, the body, femininity and rootedness in nature. Two examples that illustrate this phenomenon are provided by the notion of artistic genius and the concepts of the beautiful and the sublime.

Though the idea of genius has taken a variety of forms throughout its long history, none has countenanced a female genius. The sensitivity, intuition and even madness sometimes associated with genius contravene rationality; nonetheless genius is preserved as a masculine domain by its bold originality and by the ability of the creative artist to transcend what is given by nature or culture. In the Romantic period - arguably the time when genius was of the greatest importance in aesthetic theory - the exclusion of women from the company of geniuses was especially marked; Kant, Nietzsche and Schopenhauer are among those who discuss genius in exclusively masculine terms. (Kant notoriously remarked that a woman who aspired to higher learning, let alone genius, might as well wear a beard.) The presumption of the masculinity of genius effectively screens out women from the ranks of the most important producers of art; however skilful their creations, lacking genius, they can presumably produce little more than derivative versions of the works that define and vivify a culture.

In the formative period of eighteenth-century European theory, the category of the aesthetic itself was becoming established, and this period framed views of perception, beauty and criticism upon which contemporary theories rest. At this time, beauty and sublimity were important theoretical categories, and the language of analysis directed to these topics is consistently gendered. The experience of the sublime - unbounded, vast, awesome - was cast in terms that not only stress the adventurous masculinity of the experience but also suggest that its grasp exceeds the

capacity of the female mind. Beauty was conceived as a pleasurable, bounded, controllable object of enjoyment and described by terms such as ‘graceful’ or ‘delicate’. In fact, the bodies of women figured as examples of objects of beauty more often than females were invoked as aesthetic perceivers. Implicitly, the ideal critic was male (indeed, a heterosexual male), and judgments of beauty and taste remained masculine activities.
